CASE

Corn Harvester

- **Picks and Husks Ears**
- **Chops or Shreds Stalks**
- **Lowers Ration Costs**
- **Helps Control Borers**
- **Saves Shelled Corn**
- **Cuts Costs and Work in Seedbed Preparation**

Harvesting two crops in one operation . . . at the same time and with the same power . . . seems almost unbelievable. Yet, it's true. The new Case Corn Harvester is just such a machine—so unique in design it picks and loads ears in one wagon while chopping and blowing stalks into another—so amazingly practical that any farmer or livestock feeder can adopt the new low-cost method of feeding corn stalk silage to lower his ration costs by as much as half. For those who prefer, the chopped stalks may be fed as dry stover or even used as the best of absorbent bedding. Also phenomenal is the Case Corn Harvester's surprising feature which saves the shelled kernels ordinarily lost in mechanical picking—and it's this bushels-per-acre salvage that pays for the unit in a few hundred acres. To provide even greater savings the same base machine with other units—windrow pick-up, cutter-bar or row-crop . . . harvests all forage crops for hay, silage and daily green feeding.

Send for free Pamphlet on "Making Cheaper Beef"

If you're interested in the practice of feeding low-cost corn stalk silage and how it fits into ration requirements, just send for the booklet entitled "Making Cheaper Beef." Ask also for the Case Corn Harvester catalog which illustrates and tells how this amazing machine works . . . why it helps farmers in so many ways, including the control of corn borers, speeding the decay of tough stalks and making plowing, disking, harrowing and cultivating of the next crop on the same field so much easier. For other educational and training aids, request the pamphlet "Visual Aids to Modern Farming." J. I. Case Co., Racine, Wis.

BALANCED

From the smallest helicopter to the largest bomber MECHANICS Roller Bearing UNIVERSAL JOINTS accuracy has met every aircraft need. Designs, metals, machining, tolerances, heat treating, hardening balancing and lubrication — all have been specifically adapted for aircraft precision. Let MECHANICS universal joint engineers

help solve your control and power transmission problems. Our new catalog, containing helpful universal joint engineering data and tracing kits, will be sent to engineers, upon request.

You Need a Lasting Attachment, too!

"Till death do us part" is the way CHAIN Belt Agricultural Chain Engineers look at the design of chain attachments. They believe that there can be no weak links in agricultural implement chains and attachments ... and don't stop their work until they have the answer.

This is the principal reason why Rex® Agricultural Chain attachment links deliver such exceptional service life...last for the lifetime of the chain strand. But Rex Engineers are never satisfied, and as soon as

one development is completed, they go on to another. They've got a lot up their sleeves, and it will pay you to look for yourself.

Why not be sure you're up to date on all the recent developments designed to help you get more from the chains you use? Call your CHAIN Belt Man or write CHAIN Belt Company, 4680 W. Greenfield Ave., Milwaukee 1, Wisconsin, for your copy of Agricultural Chain Catalog No. 54-54.

**WHATEVER YOUR ROLLER
BEARING APPLICATION**

specify BOWER!

Earthmovers, jet turbine engines, rolling mill equipment, truck axles—you name it! Bower builds a complete line of tapered, straight and journal roller bearings including a size and type to fit *your* product. What's more, these dependable bearings have *proved* themselves in virtually every conceivable type of application. Their built-in quality, skillful engineering and advanced design features provide such important bearing advantages as reduced wear, longer life and lower maintenance requirements. Let a Bower engineer give you full details on the complete Bower line.

BOWER ROLLER BEARING COMPANY
DETROIT 14, MICHIGAN

BOWER TAPERED ROLLER BEARINGS INCORPORATE ADVANCED SPHER-O-HONED DESIGN! Spherically generated roll heads and higher flange with larger, two-zone contact area reduce wear, improve roller alignment and virtually eliminate "end play." This helps hold adjustment and pre-load longer and better. Larger oil groove provides positive lubrication.

BOWER STRAIGHT ROLLER BEARINGS ARE BUILT TO CARRY MAXIMUM LOADS! Integral two-lip race increases rigidity—keeps rollers in proper alignment at all times. Steel cage allows free movement of rollers between races during normal operation. High-grade alloy-steel rollers and races are precision-ground for quieter, smoother operation.

Shuts out dirt!

SAVES DOWNTIME ON BIG CAT MACHINES

Without effective seals, mud and dust would grind the life out of this D6 tractor's final drive—fast. But it's got life-saving C/R Type VD End Face Seals. They keep dirt and water out, seal transmission oil in under considerable end-play and at shaft speeds from 15 to 100 rpm. They're self-adjusting, self-aligning . . . never need take-up or attention. Proved by hundreds of thousands of field hours, these rugged C/R Oil Seals are giving longer service life to the D6 . . . saving big dollars in repairs. C/R's unequalled engineering and production facilities are at your service, too. Write for your copy of "C/R End Face Seals."

More automobiles, farm and industrial machines rely on C/R Oil Seals than on any similar sealing device

FROM CLEARING THE FIELD

Equipment Makers specify Dayton V-Belt Drives to get Top Performance

Cultivating, harvesting, preparing seed beds, baling, clearing grasslands — whatever the operation — equipment manufacturers specify Dayton V-Belt drives.

Extensive tests on many different applications have proved that Dayton V-Belts will out-perform and outlast

all others, regardless of how rugged the operation might be.

The following are typical examples of farm implement drives where Dayton Agricultural Engineers have worked with manufacturers and their designers in the laboratory and in the field to solve specific power transmission problems.

1. EFFICIENCY. Stepping up drive efficiency was a "must" in developing the Lilliston Implement Company Roto-Speed cutter for rugged grassland clearing. The answer — four raw edge Dayton V-Belts which produced maximum, continuous cutting power.

2. POWER. A space-saving V-drive that could transmit tremendous power was necessary in the development of the Robinson Blower & Engineering Corp., Bye-Hoe, 3 purpose cultivator.

Cultivating, preparing seed beds or blocking and thinning, this Dayton Cog-Belt* driven power take-off assembly assures constant trouble-free transmission.

3. ECONOMY. One of the problems in the development of the New Holland Super "77" Baler was attaining economical high speed operation. The answer was two-fold. Four harder-gripping, stronger Dayton B-Section V-Belts on the main drive at left, give highest capacity, low cost baling by transmitting every ounce of power developed. The Dayton C-Section agricultural V-Belt on the Feeder Drive, designed to slip on overload, saves wear and costly replacement of metal parts.

TO FINAL HARVEST...

4. ENDURANCE. For its No. 55 Combine, John Deere needed V-Belts that could "take it." The answer — Dayton Double Angle and Dayton Back Side Idler V-Belts, selected after three years of intensive testing. Test results established the ability of Dayton V-Belts to deliver power under the most adverse conditions of field operation.

5. VERSATILITY. Minneapolis-Moline, in the development of its Uni-Farmor Harvester, needed a Vari-speed drive belt that could supply power to several different attachments. Dayton Double-Cogs out-performed all other belts in extensive tests.

Dayton offers complete engineering service to assist you with your V-Drive problems

Whether assistance is needed in standard application or in special design, Dayton's staff of agricultural experts stands ready to work out the details with you, from drawing board to final test under field conditions.

Dayton Sales Engineers bring to every V-drive problem the skill and practical knowledge that can only be gained through working experience in every agricultural operation. Moreover, they have the advantage of the latest in technical information and the understanding of its application. Every problem, large or small, receives their prompt consideration and wholehearted cooperation.

When difficulties arise in developing new V-drive equipment or in improving present power transmission systems, remember the entire facilities of the Dayton Agricultural Division are at your disposal. Write direct to Dayton Rubber Company, Agricultural Original Equipment Division, Dept. 405, 1500 S. Western Avenue, Chicago, Illinois.

BCA PLUNGER ROLLER BEARINGS

give "smoother, more efficient operation"

on New Holland Super "77" Automatic Baler

New Holland Machine Company, Engineering Division, reports on BCA package unit bearings:

1. **Effective sealing**—proved in laboratory tests and under extremely dusty field conditions.
2. **Convenience**—sealed bearing, outer shoe, and mounting stud are all built into one compact unit.
3. **Long life in the field.**
4. **Low rate of wear**—maintain close plunger knife adjustment.
5. **Save power**—low friction results in an easy rolling plunger.

Cutaway view shows how BCA plunger roller bearings are designed into baler. Package units are built with thick-section outer ring, hardened throughout, specially adapted for rolling heavy masses on rails. Available with crowned or V-groove OD.

In this automatic pick-up baler, the plunger runs on BCA sealed, pre-lubricated ball bearings. This means fewer adjustments; lower maintenance costs; and smoother, more efficient operation for the farmer. Package units of sealed bearing, outer shoe, and mounting stud speed up and simplify assembly for the manufacturer.

If you have a bearing problem, BCA engineering cooperation and design assistance will provide the positive solution.

If you've got a bearing problem, contact:

Young Heat Transfer News

YOUNG RADIATOR COMPANY, RACINE, WIS.

Oliver Tractors with Young Radiators Stay Cool Under Full Lugging Power

Like a chameleon, Radiators are ready for just about any climate or condition you can imagine. They'll keep stationary or mobile engines cool in the Belgian Congo . . . or do a whale of a job at Little America.

Take a look at all the tools Radiators use to do a real cooling job . . . baffles, by-passes, thermostats, pressure caps, coolants. Then, there are fans, pumps and proven core designs . . . and engineering experience.

Radiator cooling eliminates needless troubles. It does away with engine hot spots, excessive oil consumption, carbon deposits, burned valves and valve seats, stuck pistons and other engine failures experienced with other types of cooling systems.

Don't be misled by the claims of other types of engine cooling systems. Remember, only Radiators can provide efficient engine cooling under every type of climate or condition.

ENGINEERING SERVICE FOR SPECIAL DESIGN APPLICATIONS

If you have a particular heat transfer problem involving any kind of agricultural equipment cooling, call or write Contract Products Division, Young Radiator Company, Racine, Wisconsin. Our Company has specialized in heat transfer engineering, product development and manufacturing for over a quarter of a century. Save your time and money . . . Write Dept. 295-F today.

Young Drawn Tank Radiators Maintain Optimum Engine Temperatures for Long Life

Oliver Corporation, Chicago, specifies rugged Young drawn tank Radiators on its Models Super 55, Super 66, Super 77 tractors.

These dependable Young Agricultural Radiators maintain optimum engine temperatures for longer tractor life. The models 55, 66 and 77 tractors are equipped with centrifugal-type water pumps, by-pass thermostats, and wet-type cylinder sleeves. Fan and water pump are located on the same shaft, maintaining air flow and water circulation in constantly equal proportion.

The Young Radiators feature full soldered, double lockseam tubes which furnish a rugged backbone to the core and extra strength to the entire Radiator. Top and bottom tanks are die-formed, bead-reinforced one-piece construction. Fabricated inlet and outlet with maximum flow area provide minimum resistance to coolant circulation.

Young Radiator Company also specializes in building engine cool-

Oliver Super 55 with baler.

NO. 6

NEW—For Smaller Vehicles

VICKERS® HYDRAULIC POWER STEERING

**SERIES S22 BOOSTER**

LOW COST

Vickers Series S22 is a new, streamlined steering booster built especially for smaller vehicles. The design permits high production economies . . . and these economies are passed on to vehicle manufacturers.

SUPERIOR PERFORMANCE

The Series S22 has excellent operating characteristics . . . providing smooth, easy, fingertouch steering under all conditions. Obstructions, chuck holes, blown tires, etc. cannot spin the steering wheel or jerk it out of control on vehicles equipped with this Booster. Safer in traffic . . . on the farm . . . in the plant.

SIMPLIFIED DESIGN

Servo valve is simplified and smaller. Ease of servicing is another advantage.

EASY INSTALLATION

Oil connections can be placed in any one of four positions (90° apart) with respect to ball stud. This and the compact design make installation exceptionally easy and reduce its cost.

NEEDS LESS SPACE

Design is unusually compact and streamlined. Series S22 will go into a minimum space and usually requires little or no linkage change.

DEPENDABLE

All the "know-how" acquired in

Vickers more than 25 years experience with hydraulic power steering has gone into the design and manufacture of the Series S22. Vickers hydraulic equipment of all kinds has a remarkable record of dependability. This booster is no exception.

ASK FOR NEW BULLETIN

A new bulletin gives more information on the Series S22 together with appropriate Vickers Pumps and typical circuit diagrams. Send for Bulletin M-5107.

For heavier steering applications and longer piston strokes, use Vickers Booster Series S23 (see Bulletin M-5106) or Model S6-315 (see Catalog No. M-5101).

VICKERS®

SERIES VT16

VANE TYPE PUMP

This is the pump normally used with the Series S22 Booster. It has integral volume control and relief valve, and oil reservoir. The vane type design delivers more oil with less power. Automatic wear compensation and hydraulic balance contribute to much longer life with minimum maintenance. No-load starting is another advantage in cold weather.

ENGINEERS AND BUILDERS OF OIL HYDRAULIC EQUIPMENT SINCE 1921

the man from Texas Foundries says . . .

**Our engineered malleable castings
are cutting costs from California
to Florida . . . can we
help you?**

Texas Foundries makes consistently uniform malleable castings for a dozen different industries in two dozen states stretching from coast to coast. Our experienced engineers have cut costs on hundreds of metal parts by redesigning for casting in malleable. Case histories are available for your inspection, and your inquiries are invited.

Texas Foundries

Organized for Service

LUFKIN, TEXAS

You can tell a Thoroughbred by Its Lines

That's right. The sleek lines of a thoroughbred are always recognizable to the expert. And with quick appraisal, the expert can accurately predict the performance promised in those lines.

Of course, when it comes to farm equipment, the farmer is the expert.

That's why farmers the country over are quick to recognize John Deere equipment as the thoroughbreds of the field—trim, efficient,

and modern equipment built to set the pace in modern farming methods.

That's why, in the wheat fields of the West, the corn belt of the Midwest, the cotton and tobacco fields of the South—from coast to coast—*wherever things grow, there is a growing demand* for quality farm equipment, equipment bearing the familiar trademark of John Deere.

MOLINE, ILLINOIS

Agricultural Implements Equipped with TRU-LAY PUSH-PULL Remote Controls ARE EASIER TO SELL

NO MAINTENANCE • BETTER APPEARANCE • MORE EFFICIENT DESIGN

BETTER OPERATION—These are some of the many benefits reported by agricultural equipment engineers who have applied these accurate and dependable remote controls on a wide range of machines and equipment

• You'll be interested in typical comments recently received from these manufacturers:

Saves Time, Labor and Material

"The use of your flexible Push-Pulls saves us a great deal of time, labor and material. The old linkages frequently required much planning in both engineering and shop which is not required now. On some of our equipment we use Push-Pulls from 10 to 30 feet in length. They operate clutch controls on the Main Power Unit, Feed Conveyors and Delivery Conveyors."

Greater Flexibility of Design

"The principal advantage of Tru-Lay Push-Pulls in our application is that they permit flexibility in locating the control valve in relation to the operator's position."

Cost Less to Install

"Tru-Lay Push-Pulls are easier and less expensive to install than linkages for remote control of power take-off,

brake and clutch. Better appearance, too."

Simple and Neat

"For several models of farm tractors, we selected your controls for their simplicity and neatness of application as governor controls."

Solution to Tough Problem

"Can be installed where straight rods are impossible... for Remote Control of transmissions, brakes and clutches."

Eliminates Maintenance

"Simple operation and elimination of maintenance problem are the major advantages in using your Push-Pulls."

Reduces Number of Parts

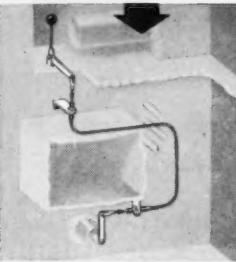

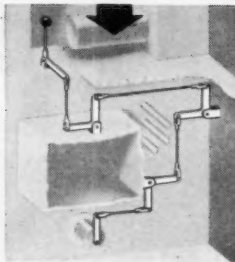

"Your Push-Pulls have eliminated links, radius rods and other lost-motion devices for remote control of hydraulic valves."

Provide ACCURATE Control

"Tru-Lay Push-Pull control cables provide minimum back-lash, even in installations up to 30 feet in length, because the cable is designed to close tolerances with minimum drag and lost motion."

TRU-LAY PUSH-PULLS are "Solid as a rod but Flexible as a wire rope." This flexibility makes it possible to snake around obstructions... permits the ideal arrangement of all elements of remote controls.

Advantages of Tru-Lay Push-Pull flexibility and simplicity are pictured below

TRU-LAY PUSH-PULL		MECHANICAL LINKAGES	
Simple One Moving Part Life-Time Service Life-Time Accuracy Low over-all Cost Noiseless		Complex Many Parts Many Points of Wear Increasing Back-Lash Loss of Accuracy Vibration Rattles	

• Engineers have adopted these accurate and dependable remote controls for use on a wide range of agricultural equipment... tractors, combines, corn pickers, corn detassler machines, corn row sprayers, orchard sprayers, tobacco picking machines, power-driven tree trimmers, and others.

Tru-Lay Push-Pulls are used for the remote control of transmissions, hydraulic and air valves, brakes, clutches, throttles, chokes, governors, power take-offs, spray nozzles, vent directional fins and on many other applications.

The six bulletins and booklets in the DATA FILE will answer all your further questions

**Push-Pull
DATA
FILE**

There is No Worry about Failures or Maintenance Costs with TRU-LAY Push-Pull Remote Controls

Long Life is a matter of record. We have never heard of a Tru-Lay Flexible Push-Pull Control wearing out in normal service. Failures, that sometimes harass users of more complex controls, are eliminated by the use of these simple, positive-action controls.

Dependable Operation of these controls is a certainty, even under the most adverse conditions... HOT as jet engines (note: Tru-Lay Push-Pulls are actually performing on hot jet applications)... COLD to 70° F below zero... SOAKIN' WET... ABRASIVE... or just plain TOUGH.

Freedom from Trouble is assured because of such features as... full protection of the inner, working member by the tough flexible conduit... lubrication of the inner, working member for life during assembly... seals that keep moisture, dust and other foreign matter out of the unit... cold swaging of fittings that makes them integral parts of the control unit.

Accuracy is inherent in the basic design of Tru-Lay Push-Pulls. They are precision products, not gadgets.

Capacity ranges from light jobs up to jobs of 1,000 lbs. input. These Push-Pulls will handle jobs 150 feet or more from the control point.

"Solid as a rod, Flexible as a wire rope" aptly describes Tru-Lay Push-Pull Controls. This flexibility provides positive, remote action whether anchorages are fixed or movable... it damps out noise and vibration... it greatly simplifies installation of controls by reducing the number of working parts and by making it possible to snake around obstructions.

Adaptability to all sorts of mechanical situations explains, in large measure, the wide-spread application of Tru-Lay Push-Pulls. Standard anchorages, fittings and heads have been designed that meet requirements on approximately 80% of the installations. Simple modifications of these standards, or minor changes in your own design, cover almost every special situation. Our engineers have the know-how on such matters, and will work with you.

For Further Information see our catalog in Sweet's Design File, write us for the DATA FILE described at the left, or ask to have a sales engineer call.

“Amazing how little this
TORRINGTON NEEDLE BEARING *costs!”*

Initial cost of the Torrington Needle Bearing is much less than that of any comparable anti-friction bearing. But economy in first cost is only the start of savings which accrue to users of the Needle Bearing.

Because of its unit construction and small size, housings and related members can be made smaller and lighter.

Ease of installation trims costs on the assembly line, too. Just a simple operation on an arbor press places the hardened outer shell of the Needle Bearing in the housing.

Throughout the life of the completed assembly, the Torrington Needle Bearing continues to pile up benefits. Low

friction, high load capacity and retention of lubricants all contribute to the characteristically long service life of Needle Bearings.

For twenty years, our Engineering Department has helped designers and manufacturers throughout industry to adapt the unique advantages of the Needle Bearing to their products. Let us help you make the Needle Bearing “standard equipment” in yours.

See our new Needle Bearing Catalog in the 1955 Sweet's Product Design File —or write direct for Catalog No. 55.

Farm Tractor Brakes

the best solution to every
Braking Problem

Automobile manufacturers, as well as truck and bus builders, have long recognized Bendix as braking headquarters for their industries. And today progressive tractor manufacturers are turning in increasing numbers to Bendix for the best solution to their individual braking problems.

There is good reason for this growing preference for Bendix Tractor Brakes. Nowhere else can be found comparable manufacturing facilities combined with an engineering experience that cover every major braking development in the past quarter of a century.*

Why not let Bendix farm tractor brake engineers help you find the best solution to your braking problems.

*Your inquiry will receive prompt attention.
Write for complete information.*

TWO United States Steel Publications

designed to help you
promote better farm fencing

Included in this planning folder are land-use scale, keys and other material necessary to help the farmer or rancher make an accurate, workable map of his property. Suggestions are also given on proper field layout to take advantage of natural contours and the space requirements demanded by modern farm machinery.

Some of the many points covered in "Fences That Pay" are the spacing, size and setting of posts, the best way to ground fence, the easiest method of enclosing a gully or run, and the most efficient type of stile to build. The farmer or rancher who follows this folder is sure to have a good, well-built fence.

These two pieces of literature are designed to aid you in helping farmers and ranchers in your area with many of their fencing problems. They are made available by United States Steel for you to pass out to fencing prospects.

The first folder, "Fence Planning Saves," is designed to be used *before* any fence is installed. It explains in detail just how to go about planning an over-all farm or ranch fence program. It shows how to handle specific problems of terrain and how to plan pastures and crop fields to get the best advantage from both.

The other booklet, "Fences That Pay," tells how to erect each specific fence. It lists all the materials necessary to do a good job, and stresses the importance of using only pressure-creosoted fence posts to get a good, long-wearing, trouble-free fence installation.

The growing use of pressure-creosoted wood by farmers and ranchers is convincing proof of the value of creosote. You will definitely promote better farm fencing if you stress the importance of using only pressure-creosoted wood.

LaBelle

DISCS

***prescription-made
by steel specialists...***

Burch Power Lift Flexi-disc on which Crucible LaBelle discs are standard equipment.

It's the *steel* in the disc you buy that counts most in its performance. That's why you can't beat Crucible LaBelle discs—they're made to just the proper toughness and hardness for top discing efficiency by steelmen who have specialized in fine steelmaking for over 50 years.

LaBelle ground edges stay sharp longer—under any soil conditions. And the *prescription-made* steel used in their manufacture gives maximum protection against failure in service.

On new equipment—or for replacements—choose Crucible LaBelle discs. They're available for *all* makes of disc plows and harrows—all soil conditions. And for your free copy of the informative booklet "Soil Improvement with Crucible Agricultural Steels," write: *Crucible Steel Company of America, Henry W. Oliver Building, Pittsburgh 30, Pa.*

Crucible Steel Company of America

Trouble-free operation at sustained, high ground speeds.

Testing New Holland's new Rolabar Rake

280 hours in a dust storm...cooked at 200°F in a furnace

To make sure this rake would operate smoothly, hour after hour, even at tractor speeds of 8 m.p.h., New Holland engineers gave the Rolabar punishment no farmer would likely ever give it.

First, the rake was sealed in a dust-tight room. A trough filled with fine powdery sand from the Arizona and California deserts was placed under the reel. A rubber tire tread was attached to the bottom of the trough.

The sand was raked by the teeth to the far end of the rake; a conveyor belt returned it to the forward end of the reel. The teeth gouged the rubber tread on every revolution as an extra test for ruggedness.

This action kicked up a dust storm no human could live through for more than five minutes. But the Rolabar Rake was going strong

under these conditions after 280 hours—the equivalent of raking 1400 acres at 5 acres an hour without stopping.

Another experiment was to find an effective sealing lubricant for the bearing shaft. It had to stand high temperatures, for some parts of the country swelter under 130° heat in the summer noonday sun.

A tine bearing shaft was placed in a furnace and subjected to temperatures reaching 200°F. The sealing grease New Holland chose retained its normal consistency and effectiveness.

Controlled tests, such as these, and extensive field-testing stand behind every New Holland machine. They're one more reason for New Holland's continued leadership in Grassland Farming. The New Holland Machine Co., New Holland, Pennsylvania.

Rolabar Rake, elevated on stand, is housed in a dust-tight room for test. A ten-horsepower motor outside the room provided power. The reel speed was approximately 100-110 r.p.m.

Bearing shaft after being cooked in a furnace at 200°F proved that the lubricant could take high temperatures as well as seal out dust.

Caterpillar Diesel D6 Tractor at work in beet field. Caterpillar Diesel Tractors use oil filters and refills made by Purolator to Caterpillar's rigid specifications.

PUROLATOR stands for

Longer Engine Life . . . More Dependable Tractor Operation

With farm acreage up in all sections of the country, efficient tractor operation is, more than ever, an economic "must."

Today's farmer places so much dependence upon his tractor that at peak activity just a half day's "downtime" can virtually wipe out his profits.

To keep "downtime" to a minimum, tractor makers today give top attention to efficient oil filtration, a vital key to dependable, long-lived engine operation.

5 reasons why more tractor manufacturers specify Purolator-built filters and refills than any other make

1. Purolator's famous "accordion-pleated" Micronic filter element has up to ten times more filtering area than ordinary types.
2. Electron micrographs prove that Purolator Micronic filters stop particles down to submicrons—.0000039 in.
3. The pleated design of the Purolator Micronic filter element provides many times more dirt storage space than old-style filters.
4. With its larger filtering area, the Purolator Micronic filter element introduces a remarkably small pressure drop into the lubricating system . . . permitting pumps of practical size and simple type.
5. With Purolator Micronic filtration, the tractor operator keeps all the oil quality he pays for. The Micronic filter element will not strip additives . . . an important advantage with HD and heat-resistant oils.

For top auger performance

LINK-BELT gives you these 5 engineering and manufacturing extras

1

STEELS MEET RIGID SPECIFICATIONS

Only selected steels are used—assuring a uniform, smooth, accurately rolled product.

2

ALL COMPONENTS AVAILABLE FOR "TAILORING" TO YOUR MACHINE

Every component can be supplied by Link-Belt, specially engineered for your requirements. This includes troughs, spouts, hangers, screws and drives.

3

CONTROLLED UNIFORMITY OF PITCH

Specialized, modern machinery assures accurate forming to produce uniform flighting.

4

ONE-PIECE, CONTINUOUS FLIGHTING

One-piece HELICOID flighting has greater smoothness and strength. Link-Belt also builds many different types to meet your special needs—cut flight, short pitch, ribbon flight, double flight to name a few.

5

STRAIGHTNESS

Straightness of completed auger is carefully checked before shipping assemblies. Then extra care is taken in handling and loading.

-----Typical LINK-BELT augers-----

Helicoid flight with plain beater

Helicoid flight

Sectional-flight

Opposed flights with center saw-tooth beater

Unmounted Helicoid flighting

This 92-page Data Book No. 2289 contains complete information. Ask your nearest Link-Belt office for a copy.

College-Industry Cooperative Research

Roy Bainer

Fellow ASAE

COOPERATIVE arrangements for research, both formal and informal, have existed between industries serving agriculture and colleges and universities for many years. The trend today is toward increasing such activity. Time has not permitted the making of a survey of the many cooperative arrangements in existence. However, correspondence with twelve selected college agricultural engineering departments revealed an active interest in cooperative research and a desire for further expansion. Some of the companies and associations now cooperating on research problems mentioned in the correspondence included Aluminum Company of America, United States Steel Corp., Reynolds Metals Co., American Zinc Institute, Fiber Glass Division of Libbey-Owens-Ford Glass Co., Lawrence Paper Co., Electro-Aire, Inc., New York Cannery and Freezers Assn., GLF Farm Supplies, Inc., New York Flower Growers Assn., Avco Mfg. Co., Gehl Bros. Mfg. Co., Edwards Equipment Co., J. I. Case Co., Tractor and Implement Division of Ford Motor Co., Deere & Co., International Harvester Co., Brillion Iron Works, The Ferguson Foundation, Jacklin Seed Co., Ryolox Corp., New Departure Division of General Motors Corp. and certain public utility companies.

No doubt the list of cooperators would have been much longer had the survey included all the publicly supported agricultural-engineering research groups. It was surprising and at the same time encouraging to find such a wide variation in cooperative effort.

In several instances, industry was supplying equipment or materials only. However, in about 80 percent of the cases reported, industry was also providing funds to assist with the work. Occasionally the financial arrangements included provisions for graduate

Paper presented at the winter meeting of the American Society of Agricultural Engineers at Chicago, Ill., December, 1954, on a program arranged by the Education and Research Division.

The author — ROY BAINER — is chairman, agricultural engineering department, and assistant dean of engineering, University of California (Davis).

*Walker, H. B. USDA Miscellaneous Publication No. 38. Research in mechanical farm equipment, December, 1928.

Urgent need for pressing the attack on basic problems of quality of product, reduction in waste, unit operations, dynamics of machines, and the like points up the opportunity for highly rewarding results from expanding college-industry teamwork in agricultural research

fellowships or for the employment of additional engineering talent.

Probably the most outstanding cooperative research effort of long duration has involved the use of electricity in agriculture. Some of the state projects have continued for more than 25 years, and, in some instances, grants-in-aid in support of the work have amounted to as much as a quarter of a million dollars. It is needless to go into detail regarding the results of this activity. Certainly the use of electricity on farms has exceeded expectations and brought about a tremendous improvement in rural living. For example, slightly more than one-half of the 67,000 horsepower-hours of energy used annually on the average California farm come from the electric power line. In summarizing the value of the California project, Dr. Robert Gordon Sproul, president of the University of California, stated: "The research in the

field of agriculture made possible by the contributions from the Committee on the Relation of Electricity to Agriculture during the past quarter century could well provide the subject matter for a book. The facts revealed by the research, and the confidence which has resulted from it, have made the California farmer one of the world's major users of electrical power, and contributed significantly to the state's ability to continue as the first or second highest agricultural producer in the nation."

In 1928, Walker* defined the position of the experiment station and the farm equipment industry in regard to research. He said in part: "The development of equipment research in our experiment stations will be of service to those

Fig. 1 University of California agricultural-engineering research engineers catching material from the straw walkers and shoe on a combine equipped for harvesting corn. Later this material was analyzed for threshing and free seed losses

industries responsible for the manufacture of farm machines. In fact, the future of farm machinery development depends upon analytical research, many phases of which cannot be developed in industrial laboratories. The nature of modern industrial manufacturing is such that the farm-equipment industry cannot resort in any great measure to the field-exploitation method of development. Volume of production in the modern manufacturing plant is of primary importance. Before volume in production can be assured, the product must be of proven value, with its commercial applications quite well defined.

"In the case of some types of simple machines the factors which should be known in advance of production can be determined by laboratory studies, but in field-operating equipment such as new types of harvesting, tillage, and seeding machines, the factors of crops, soils, climatic conditions and plant diseases may be important in determining the future value of the equipment. To prepare a factory for large-scale production without taking into account these agricultural factors would be financially hazardous, and if the products were exploited to the agricultural producer through short-sighted sales methods, the ultimate results might prove a menace to our agriculture. It is true that the up-to-date implement factory should, and does, have experiment farms to test the operating characteristics and structural features of its products, but the determination of farm-machine requirements to meet special functions such as pest control, plant-disease control, fertilizer distribution, and similar situations, where the skill and scientific knowledge of the entomologist, plant pathologist or soils expert are necessary in addition to that of the engineer, is hardly within the scope of commercial research."

In general, the points brought out in Walker's analysis sum up the situation that exists today. Fortunately in the 25 years since Walker made his report the over-all research picture in publicly supported institutions has greatly improved. The number of workers has increased, more funds are available, and the training and experience of the research worker has improved. Although there is still considerable room for improvement, the agricultural engineer today is in a particularly good position to serve industry. In the experiment station he has the support of specialists in all of the

major fields. He has recognized his dependence upon his colleagues and has been able to interest them in the cooperative solution of complex problems. He also understands their language and can interpret their viewpoint. The success of his undertakings has placed him in an enviable position on the experiment station team, with the result that generous resources are available to him. Not only can he handle the engineering phases of a problem, he is also able to serve as a coordinator with the other specialists involved.

As a general policy, the research worker in the experiment station should not attempt to develop and build equipment for direct use in agriculture. This, of course, hinges on the ability and willingness of industry to accept this responsibility. The experiment station worker, on the other hand, should be interested in the function of machines with respect to agriculture's basic needs. He should work with industry on problems that the latter is not in a position to handle. A good example may be taken from a cooperative agreement between the Avco Manufacturing Company and Cornell University. While the contact was made through the department of agricultural engineering of the University, other departments have been drawn in to get the complete information desired. Agronomy, animal husbandry, and botany are all contributing to a program of securing basic information on hay production. An economist might well have been included. Where, in industry, could a team like this be assembled?

Occasionally equipment must be developed at the experiment station level to meet local problems. In these situations full-line companies, as a rule, are not interested because of anticipated low volume. Smaller manufacturers frequently are unable or unwilling to risk the financial burden of development work. The latter group, however, is often in a position to make a new machine available as soon as basic information is developed. Usually a prototype machine is constructed by the experiment station, and once commercial production is undertaken, some consultation with the experiment station worker is required to insure the manufacture of a satisfactory final unit. These original developments often require the additional assistance of workers in the plant or animal science fields. The agricultural engineer, in this case, acts as the liaison agent between the parties in-

Fig. 2 Two views of experimental attachments developed by agricultural engineers and used in studies on adapting combines to harvesting corn. (Left) Lely attachment on a John Deere No. 55 combine • (Right) Snapping rolls attached to an International Harvester No. 64 combine

Fig. 3 Loading large bulk boxes of oranges with a tractor equipped with a fork lift — part of a study made by UC agricultural engineers, in cooperation with the citrus industry, on the possibilities for bulk handling of fruit

involved. Some typical examples are mentioned in the following paragraphs:

For several years the dried fruit industry of California urged the University to develop a mechanical apricot cutter. Their efforts to interest industry had failed. The key to the development was learning how to orient the fruit so that the sutures of the apricots would fall in one plane. The prototype machine that was eventually developed incorporated these features: the singling and orientation of the fruit; a cutting mechanism that compensated for variations in diameter; pit rejection, and final orientation of the cut fruit on the drying tray with the cup side up. Once the prototype was achieved, it was not difficult to interest a local manufacturer in building the machine.

Before an electronic color sorter could be developed for handling fruit and vegetables, some phenomenon varying with ripeness of the fruit had to be established. Scientists at the USDA Western Regional Research Laboratory aided in developing this information. Reflectance tests, made with the aid of a spectrophotometer using the complete range of the spectrum, showed a sharp dip in the reflectance curves for green lemons, for example, at a wave length of light of 6780 Angstrom units (red region of the spectrum). This dip was due to the high absorptivity of the surface chlorophyll in this region of the spectrum. Therefore, the response for yellow lemons was nil, while a maximum distortion of

Fig. 4 These four spindle-type cotton pickers were furnished by four manufacturers (Deere & Co., International Harvester Co., Ben Pierson Co., and Allis-Chalmers Mfg. Co.) for comparative field-testing purposes. The tests were a part of the cooperative programs of the U.S. Department of Agriculture and the University of California on cotton mechanization

the curve occurred for dark green lemons. The ratio of reflectance between these two extremes was 8 to 1. Fruit at intermediate stages of ripeness fell between these extremes. The establishment of this basic information was the key needed for the engineering solution of the problem, and a prototype machine capable of sorting four to five lemons per second was then built and field-tested. In establishing the basic information it was found that it took only 1/100 second to make a reading of an individual fruit. A machine, therefore, could be expected to sort at a much higher rate if the mechanics of introducing and discharging one fruit at a time could be speeded proportionately. A university-developed prototype solved the basic problem, and the machine that is now under commercial development has gone a step farther—its operating goal is set for 40 lemons per second (the equivalent of 10 field boxes per minute).

For many years the beet sugar industry tried to interest the implement industry in developing equipment for mechanizing sugar beet production. Aside from one development—which was not applicable under all field conditions—there was nothing available commercially. As a result, the United States Beet Sugar Association underwrote an over-all project on mechanization to be handled jointly by the University of California and the U.S. Department of Agriculture. When basic information was made available on seed processing, treating, planting, blocking and thinning, topping, and harvesting, several companies began to show an active interest in the problem. As soon as industry indicated its willingness to undertake a development program, the federal and state workers withdrew. Knowing when to turn such an endeavor over to industry is important. This particular arrangement worked out satisfactorily.

In most cases, such as the three examples referred to, commodity groups have assisted financially in initiating the projects through grants-in-aid. Frequently an informal agreement has been developed. The sugar beet mechanization program was carried on under a contract. In this case a provision was made for the assignment of patents to the United States Beet Sugar Association.

Departments of agricultural engineering throughout the United States have made worth-while contributions to the mechanization of agriculture. Floyd W. Duffee and his associates at the University of Wisconsin have excelled in their work on equipment for harvesting and cutting forage. Harris P. Smith at the A. & M. College of Texas has been the leader in the development of the cotton stripper. At North Carolina State College basic work has been done on the wheel-type rake. Commendable work has been done on the mechanization of potato harvesting at the University of Idaho and the University of Maine. George E. Pickard and his associates at the University of Illinois are doing basic work on the shelling of corn with combine cylinders. The University of Nebraska has a world-wide reputation in its service to industry through its tractor-testing program. Arthur W. Clyde of Pennsylvania State University has done outstanding work in his studies on hitching and on the dynamics of machines. Sugar beet machinery investigations (cooperative with the U.S. Department of Agriculture) have been centered at Michigan State College, Colorado A. & M. College, and University of California. Iowa State College has made worthwhile contributions to corn planting and harvesting. Kansas State College has been doing important work with

the heat pump. Ohio State University has made exhaustive tests on threshers and combines. Small-seed legume harvesting studies have been made at Clemson Agricultural College and the University of California. This list could be extended to cover most of the commodity fields, but space does not permit mention of the splendid work going at all experiment stations.

Since industry today seems to be trying to keep in closer touch with what is in progress at the experiment stations, a survey and catalog of research activities at the numerous publicly supported institutions should be of considerable value. Such a survey would provide short cuts to the institutions best qualified to handle specific problems requiring cooperative effort.

Until recently direct industrial cooperation has been largely limited to the lending of equipment for studies that industry has initiated. Lately, however, some impetus has begun to come from the experiment stations, and industry has responded with other kinds of assistance. For example, in the legume-seed harvesting work at the California experiment station certain problems arose during studies to adapt combines to handle clover seed. Assistance was requested from the manufacturer of a combine in general use, who assigned one of his engineers to work with the experiment station staff. This cooperative effort resulted in a satisfactory solution.

During the past year machinery manufacturers were asked to cooperate on a corn-harvesting project in California by developing gathering attachments that would make their combines suitable for corn harvesting. While all did not respond, three cooperators did make and operate their equipment in corn in 1954. The first year's trial was encouragingly successful. It is apparent that California corn can be combined successfully. This was an ideal arrangement in that manufacturers designed, built, and operated all of the necessary equipment. The experiment station staff arranged for farmer cooperators and made detailed studies of machine performance and the quality of the output. Both the agricultural engineering and the agronomy departments cooperated with industry on these projects.

Teaching and research go hand in hand. Creative research is the mechanism through which the university can fulfill its primary aim, that of enlarging man's understanding. Today industry expects creativeness in its new employees. The students in agricultural engineering must not only be well grounded in principles and practices, they must also be trained in an atmosphere of creativeness. To give them adequate training, the instructors must have the opportunity to be creative, for the teacher who is not himself creative cannot develop such ability in the student. Cooperative research, affording the opportunity for both creative thinking and a better insight into industry's problems, is a promise of more effective work from the teachers as well as from the students who will be the industrial leaders of tomorrow.

Industry's establishment of graduate fellowships offers one of the most promising means of carrying on cooperative research and at the same time aiding the teaching program. The problems to be studied should be basic to industry. The fellowships might be restricted to promising men with three to five years of experience in industry, or to outstanding seniors who want to further their education. In the latter case, industry as well as the university staff has a splendid

opportunity of sizing up the student's creative ability and estimating his chances of success in industry.

Industry and agricultural engineering departments have one thing in common. Both need men with more experience and training to solve today's increasingly complex problems. Academic training beyond the baccalaureate degree is the logical answer.

Those in research institutions supported by public funds should take inventory of their research programs. Some revision is no doubt desirable. To be of most value to industry the research should be basic in nature and well coordinated with the over-all objective of agriculture. One pitfall to avoid is that of becoming simply a testing station.

One of the large fields for intensive research is the improvement in quality of products handled under a mechanized production program. There is hardly a crop that does not show some decrease in quality when production is mechanized. Cotton is a typical example. Mechanization of the harvest has resulted in lowering the quality by one or more grade points. The solution to this problem may be in the hands of the botanist, who is striving to defoliate the crop properly before harvest to reduce the trash content of the lint; or the answer may come from the plant breeder who is working toward the development of a self-defoliating plant, or a rearrangement of bolls to get them off the ground. The weed specialist may be able to help the trash problem through improved weed-control practices. Certainly a coordinated program involving many scientists will be necessary to get a final answer.

Crop losses are staggering. These include harvest losses as well as those of storage and processing. Losses resulting from mechanization of the corn crop are appalling. Concerted effort on the part of research teams composed of workers in industry and the experiment station, including the plant breeders, is desirable.

Walker[†] has stressed the need for a balanced research program. He summed up the situation as follows: "Progress in agricultural engineering, to date, has been attained principally by the labor-saving route. . . . This has called not only for applied research, but also for development and surveys of practice. Labor saving in agriculture is still of significance, but the mechanical techniques for reducing labor for standard field operations are receiving increased attention by competent research departments in industry. . . . During the past 25 years our experiment stations have spent considerable effort on equipment development. . . . This has been justified, but the question may be raised now, if agriculture, and the industries serving agriculture, might not be better served if more attention were devoted to basic studies relating to product quality, reduction in waste, dynamics of machines, fluid mechanics problems, unit operations and the like. . . ."

"It should be a primary object in equipping for basic research to assemble staffs of great ability and high academic achievement. Surely our non-profit institutions, if they are to fulfill their responsibility for creating new knowledge, must assemble staffs containing a goodly number of highly trained men."

We must remember that research is the price of survival. How well we survive will depend upon the quality of our research.

[†]Walker, H. B., Balancing agricultural engineering research, AE, July, 1954.

Determining When to Irrigate

W. O. Pruitt and M. C. Jensen

Assoc. Member ASAE

Member ASAE

THE need for a practical way to determine when to irrigate has long been recognized. One of the most effective ways to increase irrigation efficiency on the farm is to provide the farmer with a convenient method with which he may recognize the proper time to irrigate his crops. Various devices have been developed for this purpose. Electrical-resistance-type moisture blocks and moisture-tension equipment are among the more important, and these methods have been very useful in research. They have not, however, been widely adopted by farmers.

An indirect approach to the problem involves the use of climatological data to estimate consumptive use. Blaney and Criddle (1)* developed a procedure for estimating monthly and seasonal consumptive use from temperature, daylight hours, and crop information. This procedure has been used recently by several state experiment stations to estimate monthly and seasonal consumptive use and irrigation requirements for local areas within individual states (2, 3, 4, 5, 6). Two states have proposed techniques for adapting the procedure to obtain peak daily consumptive-use rates for irrigation-system design (3, 4). Thornthwaite (7) developed a procedure for estimating consumptive use from information on temperature, latitude, days per month, and an index established locally. His purpose was to classify climate. Others (8) have used Thornthwaite's procedure for estimating daily consumptive-use rates as a guide for determining the time of irrigation. Penman (9) studied losses by evaporation from open water surfaces, bare soil and turf in England. He developed a procedure which used several climatic factors to determine consumptive use. These procedures have all received widespread recognition.

Recently consumptive-use values determined from studies on several crops at the Washington Agricultural Experiment Stations have been compared with rates of evaporation from a free water surface. Results indicate that it may be entirely feasible for a farmer to use an evaporation tank on his farm to tell when to irrigate.

This report covers comparisons of actual consumptive use for four crops at Prosser, Wash., with tank evaporation and with estimated consumptive use computed by the Thornthwaite and the Blaney-Criddle procedures. Comparisons could not be made with Penman's procedure because some of the weather data used in his method have not been recorded.

Paper prepared expressly for AGRICULTURAL ENGINEERING. Approved as Scientific Paper No. 1377, Washington Agricultural Experiment Stations, Pullman. Project No. 747.

The authors—W. O. PRUITT and M. C. JENSEN—are, respectively, assistant agricultural engineer, Irrigation Experiment Station, Prosser, Wash., and agricultural engineer, The State College of Washington, Pullman.

Acknowledgments: Aldert Molenaar, formerly professor agricultural engineering, initiated project 747 and was leader until 1952. C. E. Domingo, soil scientist, has recorded weather data since 1948. Allen Busenbark, senior experimental aide, has done much of the project field work since 1953.

*Numbers in parentheses refer to the appended bibliography.

Agricultural-engineering studies comparing actual consumptive use of irrigation water with evaporation from a free-water surface and with estimated consumptive use by the Thornthwaite and the Blaney-Criddle procedures produced results that show promise for the evaporation-pan method

Procedure

All crops were grown on a Ritzville very fine sandy loam ranging in depth from 3½ to 5 ft. This soil is underlain by an extensive layer of basalt rock which is relatively impermeable. Consumptive use was evaluated through use of soil-moisture samples taken from the entire profile from the surface to the rock. The amount of water applied each irrigation was carefully controlled to avoid overapplication and consequent free water at the rock surface. It is believed there was little opportunity for either lateral drainage or deep percolation. One exception was the 1949 alfalfa study when varying amounts of water were added at a regular frequency. Analysis of 1949 data showed some plots to be well above field capacity after irrigation. Data from these plots were omitted when average consumptive-use values were calculated.

Moisture treatments were planned on wet, medium, and dry criteria. It was intended that the medium level provide moisture for maximum yields. Time of irrigation was determined by periodic moisture sampling. Consumptive use was determined by measuring loss of moisture from the entire soil profile between irrigations and adding to this quantity any rainfall occurring during the period. Moisture samples were taken approximately one day before irrigation and from two to four days following irrigation. The average daily consumptive use between any two irrigations was determined by dividing the moisture loss plus rainfall by the number of days between samples.

The evaporation data were taken from a tank located approximately 3 miles due south of the experimental site in an environment similar to the experimental area. The tank is 6 ft in diameter, 2 ft deep, and set with the rim about 2 in above the ground surface. The surrounding surface of the weather station area has been built up by soil deposition until it is about as high as the top of the tank. The water level in the tank was maintained between 2 and 4 in from the top of the tank rim.

The Blaney-Criddle procedure can be expressed as $u = Ktp$ and $U_s = \sum u$, in which u is monthly consumptive use in inches of water, K is a crop coefficient, t is mean monthly temperature in degrees Fahrenheit, p is monthly percent of annual daytime hours (sunrise to sunset), U_s is seasonal consumptive use in inches of water, and $\sum u$ is the sum of the monthly consumptive uses during the crop growing period.

Fig. 1 Rates of consumptive use, U ; evaporation, E ; Blaney-Cridde estimated consumptive use, U_b , and Thornthwaite estimated consumptive use, U_t , for sugar beets grown under three moisture treatments in 1951

In order to compare this procedure with periodically measured consumptive use and evaporation, the t and p values were actually taken on a daily basis and summed for the measurement period.

The Thornthwaite procedure can be expressed as $e = 1.6(10t/I)^a$, in which e is the monthly unadjusted potential consumptive use (Thornthwaite's potential evapotranspiration), t is mean monthly temperature in degrees Centigrade, I is a heat index for a location, and a is approximately 0.5103. The equation is solved by use of nomograms and tables and the unadjusted potential consumptive use is adjusted for the length of day and number of days in the month. In order to compare this procedure with measured consumptive use and evaporation, Thornthwaite's adjusted potential consumptive use was computed on a daily basis and summed for actual days involved in the measurement periods.

Fig. 4 Cumulative U , $E \times 1.08$, U_b , and U_t for 1952 late potatoes from emergence to July 10 and from July 10 to the end of the growing season

Fig. 2 Cumulative U , $E \times 1.02$, U_b , and U_t for 1951 sugar beets from emergence to June 27 and from June 27 to date of harvest

Fig. 3 Rates of consumptive use, U ; evaporation, E ; Blaney-Cridde estimated consumptive use, U_b , and Thornthwaite estimated consumptive use, U_t , for late potatoes grown under three moisture treatments in 1952

The following symbols will be used:

U = measured consumptive use.

E = evaporation from USDA BPI tank.

U_b = estimated consumptive use (rate or quantity) computed by the Blaney-Cridde method

U_t = estimated consumptive use (rate or quantity) computed by the Thornthwaite method.

The following example demonstrates how the comparisons were made. Two sets of soil samples, one taken two days after irrigation and another ten days later (one day before the next irrigation) indicate an average rate of loss of 0.2 in of water per day for the ten-day period. In order to show continuous graphs, this 0.2 in per day was assumed to

Fig. 5 Rates of consumptive use, U ; evaporation, E ; Blaney-Cridde estimated consumptive use, U_b , and Thornthwaite estimated consumptive use, U_t , for early potatoes grown under two moisture treatments in 1953

Fig. 6 Cumulative U , $E \times 1.32$, U_b , and U_t for 1953 early potatoes from emergence to June 6 and from June 6 to the date of harvest

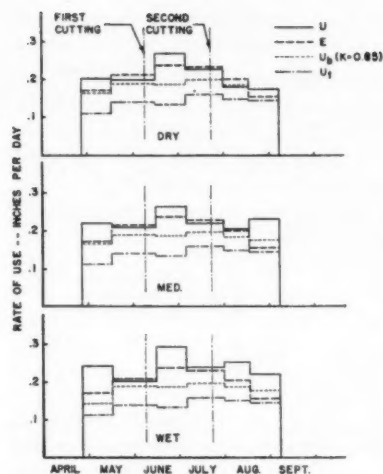

Fig. 7 Rates of consumptive use, U ; evaporation, E ; Blaney-Cridde estimated consumptive use, U_b , and Thornthwaite estimated consumptive use, U_t , for alfalfa grown under three moisture treatments in 1949

be the consumptive use rate for the entire 13 days between irrigations. To be comparative, average rates of E , U_b and U_t for the same ten days were used for the 13-day period. Consequently cumulative curves for E , U_b and U_t are slightly different for different moisture treatments.

Results

Measured consumptive-use rates for four crops are compared with tank-evaporation rates and rates of U_b and U_t in Figs. 1, 3, 5, 7 and 9. Corresponding cumulative curves for U , U_b and U_t , and for evaporation rate modified by a crop factor are shown in Figs. 2, 4, 6, 8 and 10.

For the first measured period between samplings, the value of U for sugar beets and potatoes is considerably lower than average tank evapora-

Fig. 10 Cumulative U , $E \times 1.09$, U_b , and U_t for 1950 alfalfa (May 20 to October 31)

Fig. 8 Cumulative U , $E \times 1.09$, U_b , and U_t for 1949 alfalfa (April 26 to September 7)

little ground cover, the lower consumptive-use rates during this time are reasonable.

In Figs. 2, 4 and 6 cumulative values have been broken down into two main parts, the crop-starting period and the subsequent period of good crop cover. The starting-period quantities were plotted separately in order to begin the graphs for periods of good crop cover at a common base. This was not done for alfalfa (Figs. 8 and 10) since the crop established complete ground cover early in the growing season.

In Figs. 2, 4, 6, 8 and 10, actual evaporation was multiplied by a crop factor. The factor was obtained by taking the cumulative total of U for the period of good crop cover

Fig. 11 Effect of applying constant factors to evaporation, E ; Blaney-Cridde estimated consumptive use, U_b , and Thornthwaite estimated consumptive use, U_t , to more closely approximate actual consumptive use, U (1951 sugar beets, medium irrigation treatment, Prosser, Wash.)

Fig. 9 Rates of consumptive use, U ; evaporation, E ; Blaney-Cridde estimated consumptive use, U_b , and Thornthwaite estimated consumptive use, U_t , for alfalfa grown under two moisture treatments in 1950

tion; whereas, in almost all later periods, consumptive-use rates are about equal to or greater than evaporation. Since at the start of the first period the plants were very small and provided

and dividing by the actual evaporation for the same period. Only one factor for each crop was used. It was based on the moisture treatment found to be adequate for maximum yields. This included the medium treatment for sugar beets, wet treatment for both potato crops, and medium treatment for both alfalfa crops.

Tank Evaporation as an Estimate of Consumptive Use

By noting the treatments for maximum yields in Figs. 1, 3, 5, 7 and 9 (medium for sugar beets and alfalfa, and wet for potatoes) the consumptive use is more nearly approximated by evaporation than by U_b and U_t . When a crop factor is applied to evaporation rate in Figs. 2, 4, 6, 8 and 10, consumptive use is closely duplicated.

The ratio between U and E for alfalfa changes somewhat throughout the season, probably due to the effect of cutting. During periods when a cutting was taken off, the results con-

sistently show a drop in the ratio between consumptive use and tank evaporation as compared with periods when no cuttings were removed. Since essentially all the foliage is removed each cutting, there is little chance for transpiration to take place for several days until regrowth has occurred. For the wet treatment, average ratios of about 1.3 to 1 for periods not including a cutting were found. This corresponds rather closely with results from another study made during July, 1952 (10). During a 19-day period the total consumptive use of alfalfa was 38 per cent greater than total tank evaporation. Although this 1952 work was basically a field study of the unsaturated flow of water in soils, consumptive use was calculated from the available data. Twenty comparisons, ranging from one-day intervals up to the total 19-day period, showed a regression equation of $U = 1.38E$ with a highly significant correlation coefficient of 0.99.

Estimated Consumptive Use Based on Climatic Factors

The seasonal U_b for sugar beets was 26.2 in of water whereas actual consumptive use for the medium treatment was 27.0 in as shown in Fig. 2. This indicates that for the season total the Blaney-Criddle formula was relatively precise. However, from Fig. 1 it can be seen that the underestimation of actual use in midseason has been counterbalanced by overestimation during other parts of the season, especially during the period following plant emergence.

Except for the first measured period, U_t for sugar beets runs consistently low, and for the entire season falls behind actual consumptive use totals $6\frac{1}{2}$ in for the medium treatment.

For the late potatoes (Figs. 3 and 4) results were similar to those for sugar beets. Taking the wet treatment only, which significantly outyielded the other two ($18.6 T/A$), cumulative U_b and U_t for the period of good crop cover fell short of actual consumptive use by 5.0 and 6.4 in, respectively, during the good crop cover period. These differences are decreased when the starting period (the period prior to good crop cover) is included. The difference between values for estimated and actual consumptive use was greater for early potatoes (White Rose) as shown in Figs. 5 and 6. In the wet treatment, which gave the best yield, ($19.1 T/A$) U_b and U_t values were only about 60 and 54 percent, respectively, of actual consumptive use.

Fig. 12 Totals of E , U_b , and U_t for the month of July from 1924 through 1954 and measured consumptive use, U , for alfalfa for July of 1949, 1952, 1953, and 1954

From Figs. 7, 8, 9 and 10 it is apparent that U_t is seriously under actual consumptive-use values for alfalfa at this location. The Blaney-Criddle method was somewhat better for alfalfa than for sugar beets or potatoes.

Figs. 2, 4, 6, 8 and 10 suggest that a crop factor might be applied to U_b and U_t and make them more nearly approximate actual consumptive use. Fig. 11 for the 1951 medium treatment on sugar beets is included to indicate a representative comparison. When U_t was multiplied by a crop factor of 1.42, a cumulative curve nearly as good as $1.02E$ is obtained. If the crop K value in the Blaney-Criddle procedure is changed from the recommended value of 0.75 for sugar beets at Prosser to 0.88, the accuracy of the estimate is considerably increased, but estimates for July and August still fall quite short. A crop factor of 1.5 for late potatoes and 1.94 for early potatoes correlated U_t well with U . Corresponding best-fit crop factors, K , for U_b were 1.03 and 1.30.

As recognized by Criddle (11) a crop coefficient which would vary throughout the season could be applied to better correlate the Blaney-Criddle procedure with consumptive use. At this location, for example, the crop coefficient K , in

TABLE 1. CORRELATION BETWEEN U AND E , U_b AND U_t AND REGRESSION EQUATIONS FOR PERIODS OF GOOD CROP COVER

NOTE: All correlation coefficients are highly significant.

the equation $u=Kip$, should vary from about 1.1 in July to 0.6 in September for the 1951 sugar beets.

Fig. 12 is a summary of the monthly totals of E , U_b , and U_t based on weather records for the month of July throughout the last 31 years as compiled by Nelson (12) and others. The July 1949, 1952, 1953, and 1954 values for consumptive use for alfalfa (extrapolated from measured periods of good crop cover) are also plotted. The changes in evaporation, E , from year to year are not similar to the changes in U_b nor U_t in several instances. The curves indicate that other important factors influence evaporation besides those used in determining U_b and U_t . The limited consumptive-use information for alfalfa indicates trends similar to those for evaporation.

Statistical Evaluation

The rates of consumptive use which have been presented in all the graphs are mean values for treatments only. Table 1, however, presents the statistical results for the row crops during periods of good crop cover for all comparisons made between consumptive use and E , U_b , and U_t . Values of consumptive use were taken from individual plot measurements rather than treatment means and are based on soil samples taken from three locations per plot.

From Table 1 it is found that all correlation coefficients exceed the one per cent level of significance. Actually from a practical standpoint, some measurement would be preferable which would give an estimate equal to the consumptive use, or related to it by a constant ratio throughout the season. Expressed graphically it would be desirable to have a straight-line relationship between actual and estimated use which would pass through the origin.

Conclusions

By applying a constant factor for each crop, tank evaporation was adjusted to closely estimate actual consumptive use. For moisture treatments giving high yields in row crops, the adjusted cumulative evaporation remained within $\frac{3}{4}$ in of the actual measured consumptive use throughout the season of good crop cover. Consumptive use dropped off with drier moisture treatments, but the decrease was not large unless yields were materially lowered. The variation between U and adjusted E was slightly greater in alfalfa than row crops, probably because of the effect of cuttings. The favorable correlation between E modified by a crop constant and U indicates promise for development of evaporation equipment that a farmer could use to tell when to irrigate.

The Blaney-Criddle and Thornthwaite methods departed appreciably from measured consumptive use in this work. There is apparently some hazard in applying these procedures without checking to determine their applicability at a location, especially if they are to be used to schedule irrigation. A crop factor applied to the Thornthwaite procedure would have merit.

Tank evaporation, being influenced by many of the same factors which determine consumptive use, should be expected to be more effective in estimating water requirements than methods which depend on fewer of the climatic factors involved. The reported work, however, is only preliminary in nature and study is needed before recommendations for

usage should be considered. Adapting a convenient tank usable to the farmers, establishing a proper tank environment, and relating evaporation to consumptive use by suitable crop factors are items needing study. From this work, however, it is believed that the direct use of evaporation data in estimating consumptive use and the application of them for scheduling of irrigation, offers considerable promise.

Summary

Rates of consumptive use of water by four crops grown at the Irrigation Experiment Station at Prosser, Wash., are presented. Rates of evaporation from a USDA, BPI evaporation tank, along with the estimated consumptive-use rates using the Blaney-Criddle and Thornthwaite procedures, are compared with measured consumptive-use rates.

During periods of good crop cover, tank-evaporation rates gave a much closer estimate of actual consumptive-use rates than either the Blaney-Criddle or Thornthwaite procedure. Although high correlation coefficients resulted from statistically comparing each of the three methods with consumptive use, it was found that for the Blaney-Criddle method the value for the crop coefficient should vary throughout the season. Estimates of consumptive use with the Thornthwaite procedure fell short of actual consumptive use, but by applying a constant crop factor, depending on the crop, they were adjusted to provide closer correlation.

Comparisons of the past 32 years' evaporation data during July with estimated consumptive use and with actual consumptive use for alfalfa during four of the last six years, indicates some problem in adjusting the Thornthwaite or the Blaney-Criddle procedure for this area, especially for scheduling irrigation. The quite favorable results obtained with the evaporation pan show promise that this principle may be applicable in determining when to irrigate.

Theoretical Aspects of Water Spreading

Warren A. Hall

Member ASAE

WATER spreading on agricultural lands for purposes of recharging underground water reservoirs with excess winter surface flow has introduced a number of problems. Generally speaking agricultural soils are much less permeable than natural aquifer outcroppings. Furthermore, the permeability of the surface soil is greatly affected by many factors including working of the soil, natural and planted vegetation, amount and type of organic matter, changes in chemical and physical properties of the soil and the growth of microorganisms(1).^{*} Considerable excellent research has been done by the Agricultural Research Service (USDA), the Kern County Land Company and the North Kern Water Storage District on the behavior of the soil surface under prolonged submergence and the reaction of infiltration rates to various surface soil-treatment programs in the spreading basins. This research is summarized in papers by Bliss and Johnson (2) and by Schiff (3) and is continuing. The purpose of the present paper is to discuss from a theoretical point of view some of the effects of variation in permeability of the soil with depth on the prolonged submergence infiltration rates. In addition, a method is proposed for the analysis of a prospective location for water spreading, including an evaluation of the degree to which benefits from surface treatments may be expected.

A theoretical approach to water spreading and infiltration does not imply a derivation of a set of exact equations from which proper design can be computed. Rather, from the application of principles of fluid mechanics to certain simplified or ideal systems, qualitative results may be obtained which may be used for design purposes from a "greater than" or a "less than" standpoint. More rarely, one may obtain quantitative results which may be used to establish the "equal to" criterion for design.

Paper prepared expressly for AGRICULTURAL ENGINEERING.

The author—WARREN A. HALL—is assistant professor of irrigation, University of California (Davis).

Fig. 1 Soil moisture zones during infiltration

Adequate design of a system for water spreading on agricultural lands requires a reasonable knowledge of the substrata and their permeabilities as well as the characteristics of the surface soil

MOISTURE ZONES DURING INFILTRATION

Laboratory experiments on one dimensional infiltration from a ponded water surface into a uniform soil column have been described by Bodman and Colman (4) and others (5). From these descriptions the soil water system can be subdivided into four more or less distinct zones as indicated in Fig. 1. Just below the ponded water surface is a very shallow zone in which the pressure in the liquid is at or above atmospheric pressure. In the subsequent discussion this zone will be referred to as the saturated zone. The lower boundary of this zone will be called the saturation surface and is defined as that surface in the soil where the pressure in the water phase is equal to atmospheric pressure and above which the pressure is greater than atmospheric pressure. The second zone may be termed the transmission zone. Water is transmitted through this zone at pressures less than atmospheric. The energy gradient over much of this region appears to be very close to unity. The third zone might be termed the wetting zone and is characterized by a rapidly decreasing moisture content with depth as contrasted with the transmission zone with nearly constant moisture content. The fourth zone consists of the portions of the soil which are not yet visibly affected by the infiltration. This zone may be termed the dry zone.

ONE-DIMENSIONAL INFILTRATION

One-dimensional infiltration may be analyzed by applying the Darcy equation to the flow in the saturated zone. Let the velocity be denoted by V and defined as the quantity of flow per unit time per unit area normal to the flow. The head at the lower limit of the saturation zone, i.e., the saturation surface, is zero by the definition of the saturation surface if the datum for elevation is taken on this surface. If the thickness of the saturated zone is z and the depth of water over the soil is d , the head on the upper boundary of the saturation surface is $d+z$ (Fig. 2). By the Darcy equa-

Fig. 2 Head loss in the saturated zone

tion, the velocity is equal to the permeability K multiplied by the head loss per unit distance.

$$V = K(d+z)/z \quad [1]$$

The infiltration rate is defined as the quantity of water per unit time per unit area which enters the soil surface. Thus for one dimensional flow the velocity determined by equation [1] is the infiltration rate. Equation [1] is the equation of a hyperbola with asymptotes $V=K$ and $z=0$. Therefore, as the saturation surface penetrates more deeply into the soil, the infiltration rate will decrease, approaching asymptotically a value equal to the permeability.

If the saturated permeability K_s remains constant throughout a soil of infinite depth, the penetration of the saturation surface for one-dimensional flow can be shown to be a continuously increasing function of time. Hence, even under ideal conditions of a stable soil and sterile system, the infiltration rate for one-dimensional flow may be expected to decrease with time. Equation [1] gives the rate of flow through the soil surface. Because of incompressibility, this is also the rate of flow past the saturation surface. Experimental data show that in at least part of the transmission zone the energy gradient is very nearly unity and the permeability is not greater than the saturated permeability. However, the gradient in the saturated zone is always greater than unity, hence more fluid flows into the top of the transmission zone than can flow through this zone. A positive difference between inflow and outflow rates indicates that fluid is accumulating in the intervening space. Ultimately this space will become saturated because of this difference.

An equation expressing this relationship may be written. Denote by Q the volume of water accumulating in this space per unit time. Then, for a cross sectional area A , a transmission zone permeability of K_t and a saturated zone permeability of K_s

$$Q = A[K_t(d+z)/z - K_s] \quad [2]$$

In the usual water-spreading problem the surface permeability K_s is far from constant but decreases with time due to colloidal swelling, microbial activity, etc. The effect on the penetration of the saturation surface can be noted from equation [2]. As K_s decreases for the reasons cited above, the term in the brackets will approach zero, reach zero and become negative. When it becomes zero the rate of accumulation is zero and the saturation surface will cease to advance. When the bracketed term becomes negative, the outflow from the transmission zone exceeds the surface inflow and the saturation surface will recede until the term is again zero. Because of this action, the saturation surface probably does not penetrate more than a small fraction of the pond depth on untreated soils.

INFILTRATION INTO STRATIFIED SOILS

Very few soils are uniform to any great depth. Those soils in many water-spreading areas have marked stratification. There are three major effects of stratification which will be treated in the subsequent paragraphs. The first effect is the creation of perched water tables above the less permeable strata. The second effect is the possible stabilization of saturation surfaces at the interfaces of less permeable

Fig. 3 Schematic diagram of a perched water table

layers above more permeable ones. The third effect is to change the effective permeability of a region containing several strata.

Perched Water Tables

In most stratified soils there will exist one or more layers whose permeability is less than that of the overlying area. The rate at which such layers are able to transmit water is often less than the rate water reaches the layer from above. A perched water table results and continues to grow until the combined effects of increased area due to lateral flow and increased energy gradient are sufficient to transmit water through the less permeable layer as rapidly as it is received from above.

As shown in Fig. 3, the perched water table in many respects is a subsurface spreading pond with a depth of water δ corresponding to the positive pressure head at the top of the less permeable layer. If the layer of soil immediately below is not saturated, a saturated zone and saturation surface will develop within the less permeable layer. Let ζ represent the depth of penetration of the lower saturation surface, K_2 the permeability in the lower saturated zone and δ the head corresponding to the positive pressure at the top of the less permeable stratum. The velocity V_2 at which fluid will be transmitted through a point in the surface of this stratum is

$$V_2 = K_2(\delta + \zeta)/\zeta \quad [3]$$

Stratigraphic Effects on Penetration of Saturation Surface

The saturation surface may be prevented from moving downward into the soil by the presence of a more permeable layer underlying a less permeable one. Equation [2] is applicable to this situation if K_s and K_t are replaced by K_1 and K_2 , the permeabilities of the upper and lower layers, respectively:

$$Q = A[K_1(d+z)/z - K_2] \quad [4]$$

Applying the same reasoning developed in the previous section for variable surface permeability, the saturation surface will cease to penetrate deeper into the soil when the term in the brackets is zero. When the value of z is approximately equal to the depth z_1 to the bottom of the less permeable

stratum, the saturation surface cannot penetrate further if the ratio of K_1 to K_2 is such that

$$K_2/K_1 = (d + z_1)/z_1 \quad [5]$$

It follows from equation [5] that after moderate penetration, very little increase in permeability is required to stabilize the saturation surface until the saturated zone merges with a water table building from below. This latter action possibly accounts for some of the observed abrupt decreases in infiltration rate.

Effective Permeability of a Series of Strata in One-Dimensional Flow

The third effect of stratification is to render equation [1] for infiltration into uniformly permeable soils invalid. It may be replaced by an equivalent expression involving the concepts of effective permeability and effective length of flow path. For one-dimensional flow, the velocity through each successive layer in the saturated zone is a constant. For each layer (denoted by the index i)

$$V = \Delta b_i K_i / L_i \quad [6]$$

The total head loss through n such layers is

$$\Delta b = \sum_{i=1}^n V L_i / K_i \quad [7]$$

The terms of the sum can be reduced to a common denominator by the introduction of a reference permeability and an effective distance of flow.

$$(L_e)_i / K_e = L_i / K_i \quad [8]$$

The total head loss is thus equal to

$$\Delta b = V / K_e \sum_{i=1}^n (L_e)_i \quad [9]$$

The rate of flow through the strata occupied by the saturation zone is, therefore,

$$V = K_e (d + z) / \sum (L_e)_i \quad [10]$$

A similar equation may be written for vertical flow in perched water tables.

INFILTRATION WITH LATERAL FLOW

The downward flow under the central portions of very large spreading ponds is essentially one dimensional. Flow under small ponds will in general have both horizontal and vertical components. The simplified one-dimensional equations are no longer valid and must be replaced. The Darcy equation in its most general form remains valid, but its application is considerably less straightforward. However, it is possible to discuss some of the effects of lateral flow on infiltration rates and spreading pond design by the use of simplified equations.

Effect of Lateral Flow on the Saturated Zone

Capillary forces on the edges of the saturated zone produce a component in the hydraulic gradient in the horizontal direction. The resulting lateral flow creates a system of streamlines which diverge in the direction of flow. As they diverge within the saturated zone, the equation of continuity requires that the magnitude of the velocity decrease. At the same time, the minimum hydraulic gradient in the vertical direction is unity provided the saturated zone has not merged

with a water table. Thus there is a minimum vertical component of the velocity which, by application of the Darcy equation, is equal to the permeability. Therefore, there must be a maximum permissible divergence of streamlines within the saturated zone. Consider a single expanding stream tube whose cross-sectional area at the surface is A_s and at a point p within the saturated zone is A_p . By the equation of continuity

$$V_p = V_s A_s / A_p \quad [11]$$

A vector is always equal to or greater than one of its cartesian components. Therefore, the least value of V_p obtainable will be equal to or greater than its vertical component. The vertical component is in turn greater than the permeability in the saturated zone. Thus for a point p in the saturated zone,

$$V_p \geq K_s \quad [12]$$

By combining equations 11 and 12, the maximum possible cross-sectional area at a point p within the saturated zone is:

$$A_p \leq V_s A_s / K_s \quad [13]$$

The streamlines, therefore, cannot diverge to an area greater than that given by equation [13], except by a decrease in K_s along the stream tube. This can occur in a uniform soil only by a decrease in moisture pressure to a value below atmospheric. Equation [13] thus also defines the maximum penetration of the saturation surface if the streamline pattern can be estimated for the saturated zone, e.g., by the use of flow nets. The effect of lateral flow is thus seen to result in prolonging the higher infiltration rates by limiting penetration of the saturation surface. Let L be the length of a stream tube in the saturated zone. Then with the point p on the stabilized saturation surface at a depth z below the soil surface, the velocity of infiltration is approximately

$$V_s = K_s (d + z) / L \quad [14]$$

Substituting equation [14] into [13],

$$A_p / A_s \leq (d + z) / L \quad [15]$$

Since L is usually of the same order of magnitude as $(d + z)$, little divergence of streamlines will occur before the saturation surface is reached. Equation [15] would also indicate that small ponds will be much more responsive to surface treatment and to variations in depth of the water in the pond. This conclusion appears to be substantiated by experimental data of the USDA Agricultural Research Service and the North Kern Water Storage District.

Lateral Flow in Perched Water Tables

As water accumulates locally above a less permeable layer, energy gradients are established in the horizontal direction as well as in the vertical direction. Under these gradients lateral flow will occur, increasing the area of perched water zone. The accumulation is a complex unsteady flow problem, and the shape of the water table at any time is unknown. Under prolonged infiltration it is possible that an equilibrium will be reached during a spreading season. For this condition estimates of the possible area of the perched water zone may be made.

Equation [3] previously presented is an expression for the velocity at a point through a stratum supporting a perched water table. The total quantity of flow can be obtained by integrating this velocity over the area A_2 covered

by the perched water table. Thus the total rate of outflow Q_2 from the perched water table at any time is

$$Q_2 = \int_{A_2} K_2 (\delta + \xi) / \xi \quad [16]$$

Referring to Fig. 3, δ is equal to the depth H of the perched water zone less the head loss resulting from flow between the top and bottom of the perched water zone. As an approximation, this head loss is equal to that which would occur if the velocity V_2 were the only velocity through the perched water zone. That is,

$$b' = K_1 H / V_2 \text{ (approximately)} \quad [17]$$

The rate of inflow through the soil surface is also obtained by integration of the velocity through the surface over the area of the spreading pond.

$$Q_1 = \int_{A_s} K_s (d+z) / L \quad [18]$$

The maximum growth of the perched water zone will have occurred when the total outflow from the perched water table is equal to the total inflow from the surface:

$$\int_{A_s} K_s (d+z) / L = \int_{A_2} K_2 (\delta + \xi) / \xi \quad [19]$$

Equation [19] cannot be integrated directly, but the integrals may be eliminated by replacing the terms representing the hydraulic gradients by their average values with respect to the corresponding area. Denoting the averages by a bar over the quantity, equation [19] becomes

$$K_s A_s \overline{(d+z)/L} = K_2 A_2 \overline{(\delta + \xi)/\xi} \quad [20]$$

The average gradient at the surface can be determined from an estimated total infiltration rate for the area. The average gradient below the perched water table cannot be so estimated since the area A_2 is unknown. However, a range of possible variation of the average gradient can be determined, thus giving an "at least" and an "at most" value for the amount of lateral spreading at a perched water table. This value is important for the design of water-spreading basins for it indicates what, if any, spacing of successive ponds will give a minimum of interference between basins.

The "at most" value of A_2 corresponds to the minimum possible average hydraulic gradient through the less permeable zone which has created the perched water table. The minimum value is unity in this "lower saturated zone" (Fig. 3). Thus the "at most" value for A_2 is given by substituting an average gradient of unity in the right side of equation [20].

$$A_2 (\text{at most}) = A_s \overline{(d+z)/L} K_s / K_2 \quad [21]$$

The "at least" value for A_2 is of course equal to A_s . Under equilibrium conditions, equal inflow and outflow rates from the perched water zone may under some circumstances give an "at least" value for A_2 which is greater than A_s , thus further limiting the range of variation. The largest hydraulic gradient which can exist in the less permeable layer will determine the "at least" value for A_2 provided that the "at least" value so determined is greater than the area A_s of the pond at the soil surface. Since most microorganisms will be filtered near the soil surface, decreases in permeability due to this cause can be expected to be a minimum. Furthermore, if

the site is at all suitable for water spreading, the less permeable layer should be relatively thin. Let it be presumed, as a first approximation, that the saturation surface at equilibrium has reached the bottom of the less permeable layer. Let the thickness of this layer be L_2 . Equation 20 becomes

$$K_s A_s \overline{(d+z)/L} = K_2 A_2 (\delta + L_2) / L_2 \quad [22]$$

The largest hydraulic gradient is seen to be obtained for the maximum value of δ , the average head on the top of the less permeable layer. In addition, from Fig. 3

$$\delta = (H - b') \quad [23]$$

The maximum value of δ is obtained with a maximum value of H . In turn H is restricted only by the distance from the upper saturation surface to the less permeable zone. (Note that if H is greater than this distance, the upper saturated zone and the perched water zone merge thus affecting adversely the surface infiltration rate.) The "at least" value for A_2 is therefore

$$A_2 (\text{at least}) = A_s \overline{(d+z)/L} [L_2 / z_2 - b' + L_2] K_s / K_2 \quad [24]$$

where z_2 is the distance between the upper saturation surface and the less permeable layer creating the perched water table. If equation [24] yields a value less than A_s , the "at least" A_2 is equal to A_s .

Equations [21] and [24] determine the range of variation of lateral flow in perched water tables. If equilibrium between inflow and outflow is not reached during the spreading season, smaller amounts of lateral flow should be expected. The approximate value of A_2 for design purposes can be estimated fairly accurately by these equations.

Conclusions

Equations [1] and [2] demonstrate that infiltration rates will decrease with time for uniform, stable, sterile soil-water systems. Equation [5] demonstrates that only small changes in permeability are necessary to stabilize the saturation surface at a point near the soil surface thus eliminating the decrease in permeability with time predicted for uniformly permeable soils. Lateral flow is also shown by equation [15] to limit penetration of the saturation surface thus prolonging high infiltration rates under small ponds. Small ponds should thus be expected to respond much more favorably to surface treatment and increases in pond depth. Finally a range of variation in lateral flow in a perched water table is given by equations [21] and [24]. It may also be noted by inspection that certain field conditions favor validity of one or the other of these equations. For example, under extremely large spreading ponds, the mean hydraulic gradient through the less permeable layer will tend nearer to the maximum. In such a case efficient use can be made of the vertical distance z_2 (equation [24]) to supply the necessary gradient to put a large quantity of water through the less permeable layer. If, in addition, z_2 is rather large (i.e., a deep-lying less permeable layer), considerable benefit can be expected from the use of large spreading ponds and equation [24] will be somewhat more accurate for computing lateral spread. On the other hand, if z_2 is small (i.e., a shallow-lying less permeable layer), there is less benefit to be derived from large ponds. Small ponds, as proposed by Schiff(6), whose spacing will be more closely dictated by equation [21], may be more suitable. (Continued on page 399)

Ammonia Loss from Sprinkler Jets

D. W. Henderson, W. C. Bianchi and L. D. Doneen

APPPLICATION of soluble fertilizers through sprinkler systems is of considerable interest because of the possibility of reducing costs by eliminating special operations for fertilizer application. However, it is well known that ammonia is a volatile substance, and that its escape from a solution to the atmosphere may occur in varying degree. Because of this fact farmers have been warned not to attempt application of anhydrous or aqua ammonia through sprinkler systems. It has not been so universally understood, however, that any solution which contains ammonium ions (NH_4^+) also contains free ammonia (NH_3) which is subject to loss through volatilization. The aim of the investigation reported here was to determine the magnitude of possible losses of common ammoniacal fertilizers. Some of the factors affecting these losses were studied so that recommendations could be made for reducing them to a minimum.

Experimental Procedure

The various solutions studied were made up with tap water in a 100-gal galvanized iron tank and pumped from the tank through a small, slow-revolving part-circle-type sprinkler set to distribute water through an arc of about 25 deg. Sixteen glass catch vessels approximately 6 in in diameter were placed at intervals of 2 ft along the axis of the pie-shaped area covered by the sprinkler. A few grams of boric acid powder were placed in each catch vessel to prevent loss of ammonia from the vessel during the run, which was of 25 to 30 min duration, and during subsequent handling.

Shortly after the beginning of each run, a sample of the solution passing through the sprinkler nozzle was taken. The temperature and pH of the solution were determined

Paper presented at the annual California Sprinkler Irrigation Association conference at Fresno, Calif., February 1955.

The authors—D. W. HENDERSON, W. C. BIANCHI and L. D. DONEEN—are, respectively, assistant irrigationist, research assistant, and irrigationist in the department of irrigation, University of California (Davis).

Investigation shows that the nearer neutral the pH of the fertilizer solution is kept, the greater the probability that all losses will be reduced to a minimum

immediately, and the ammonia concentration measured by distillation and titration. The solutions in the catch vessels were composited for ammonia determinations. Losses of ammonia were computed from differences in concentrations of samples taken from the sprinkler nozzle and concentrations of ammonia in the catch vessels. These observed losses were corrected for water loss by evaporation. Correction was accomplished by determining the increase in chloride concentration from the nozzle to the catch vessels. Since the chloride content of the irrigation water used was low, enough sodium chloride was added to bring the total chloride up to 150 ppm. This chloride concentration is convenient for analysis, but is not sufficient to lower the vapor pressure of the water appreciably.

Since losses from the catch vessels were prevented by addition of boric acid, the values reported are limited to volatilization from the jet. Field application would result in greater losses since interception of water by crop foliage would allow more time for ammonia escape. Furthermore, losses from small droplets which drift out of the catch area would probably be greater because they are in the air for longer periods than that retained in the catch vessels. Losses from soil were not considered in this study since they presumably are small as long as the soil remains moist and are probably similar in magnitude to those incurred in broadcast methods of fertilizer application.

A few tests were made with an operating pressure of 60 psi at the sprinkler, but in most instances the pressure was 40 psi. Tests were carried out at both these operating pressures using the same fertilizer solution, and it was concluded

Fig. 1 Losses of aqua ammonia in relation to concentration of ammonia in the irrigation water

Fig. 2 Losses of ammonia from fertilizer salts in relation to ammonia concentration in the irrigation water

that the effect of operating pressure was small under the conditions of these trials.

Wind velocity, air temperature, and relative humidity were recorded for each test. Although no special attempt was made to study the effect of these climatic conditions on ammonia losses, it was observed that variations in duplicate determinations made under different weather conditions bore no consistent relationship to changes in the weather.

Solutions were made up from commercial fertilizers except for aqua ammonia for which ammonium hydroxide was used.

Results and Discussion

Losses of ammonia from aqua ammonia, ammonium sulfate, ammonium nitrate, and monoammonium phosphate were studied in relation to the initial concentration of the fertilizer solution. The results with losses expressed as percent of the initial concentration (pounds of ammonia per acre-inch of water) are given in Figs. 1 and 2.

As would be expected, losses from aqua ammonia solutions were very high, and increased with initial concentration. Losses from solutions of ammonium salts were appreciable at low initial concentrations, but decreased rapidly as the initial concentration was increased. Losses from ammonium nitrate and phosphate were essentially the same at equal ammonia concentrations and are represented by a single curve in Fig. 3. Losses from ammonium sulfate were appreciably higher.

Differences in the pH of the solutions after addition of the fertilizer materials accounts for much of the effect of initial concentration on ammonia losses. The tap water used to make up the solutions had a pH of 8.3. Addition of aqua ammonia increased the pH, but addition of the fertilizer salts studied decreased the pH through hydrolysis and the action of acidic materials remaining in the fertilizer salts from the manufacturing process. The observed losses of ammonia are shown in Fig. 3 in relation to the pH of the fertilizer solution. These data indicate that, if ammonia losses from sprinkler jet are to be kept below 10 percent, the pH of the fertilizer solution should be 8.0 or less; approximately 5 percent loss can be expected at pH 7.5, and loss is negligible if the pH is 7.0 or below.

Many factors will affect the pH resulting from addition of fertilizer salts to a given irrigation water. The most

important of these are the pH of the water, buffer capacity of the water (particularly $\text{CO}_3^{--} + \text{HCO}_3^-$ content), the acidity of the fertilizer salt, and the amount of fertilizer added to the water. Since irrigation waters vary in pH and buffer capacity and fertilizer salts vary in acid content, the simplest procedure for controlling losses would be to determine the pH of the irrigation water after the addition of fertilizer materials. The use of commercial indicators in the form of paper strips would make possible rapid field checks.

More general recommendations can be made. If the irrigation water is essentially neutral (pH less than 7.5), addition of any acidic ammonium salt in appreciable quantity will reduce the pH to the extent that losses would be negligible. If the water has a pH of much above 7.5, losses can be reduced to a minimum by applying the fertilizer in the smallest possible amount of water which will not result in injury to the crop or sprinkler system.

The temperature of the irrigation water would presumably affect ammonia losses. A series of tests carried out with the same fertilizer solution (ammonium sulfate, 14 lb per acre-inch) at temperatures of 68, 77, and 90 F gave observed losses of 5.2, 6.6, and 7.6 percent, respectively. Losses may therefore be expected to increase as the water temperature increases. The water temperature for all other tests reported was approximately constant at 79 F.

Summary

Some of the factors affecting losses of ammoniacal fertilizers from sprinkler jets were investigated. The principal consideration is the pH of the fertilizer solution, which depends on characteristics of both the irrigation water and the fertilizer materials.

It should be emphasized that field application of ammonia fertilizers results in losses other than those from the jet. If the pH of the fertilizer solution being applied is kept as near neutral as practicable, it is probable that all losses would be reduced to a minimum.

Water Spreading

(Continued from page 397)

It is apparent that an adequately designed spreading system requires a reasonable knowledge of the substrata and their permeabilities as well as the characteristics of the surface soil. In this respect, a small pipe jetting rig such as described by Reger et al(7) should prove to be a valuable supplement to well logs taken in the vicinity of a proposed spreading site.

Tile Drainage of Sloping Fields

Herman Bouwer
Assoc. Member ASAE

IN SLOPING fields, a tile line or a system of equidistant tile lines (laterals connected by a main) can be installed at different directions with respect to the contour lines. They can run parallel (transverse drainage), perpendicular (longitudinal drainage) or at some angle between 0 and 90 deg (oblique drainage) with the contours.

In the literature, numerous examples are given of heterogeneities in the soil (outcrops of pervious or impervious layers, old streambeds in constructional landforms, etc.), together with recommendations as to how to drain the local wet areas caused by these heterogeneities. It is often difficult in those cases to determine which situation occurs in a particular field. Once it has been determined, however, the drainage then is generally obvious. Furthermore, it is generally agreed that tile for intercepting foreign water should be installed parallel with the contours. In the case of uniform isotropic soils, however, where a uniform excess moisture calls for a systematic drainage system, contradictory recommendations and arguments with respect to the proper direction of the laterals have been presented.

The question of longitudinal versus transverse drainage has been approached from different points of view. Most authors agree that the chance of sedimentation in the mains is less in the transverse systems, the mains having steeper slopes than the laterals. Transverse systems, however, may be hard to install if the slopes of the laterals become too flat. It has furthermore been argued that transverse systems are to be preferred from a standpoint of surface runoff (27)*. Recommendations for maximum and minimum tile grades may lead to the adoption of either system, depending on the slope of the field.

The most controversial aspect has been the rate of groundwater movement into identical longitudinal and transverse systems in uniform soils. Vincent (32) and others stated that, with transverse lines, part of the water seeps back into the soil at the downhill side of the tile after it has entered it at the uphill side. Next, Merl (19) and Gerhardt (14) claimed that transverse systems have a greater draining capacity. Gerhardt later abandoned this view (27), but the same argument, although explained in a different way, has been presented in the British literature (16, 20). The recent German literature (23, 25, 26) still recommends transverse systems.

Chronologically, before 1890 it was generally agreed that the longitudinal system was best (11, 18, 32, 34), possibly as a result of existing practices with stone drains. The sensitivity of stone drains to sedimentation and their high hydraulic resistance made installation with the steepest possible gradient necessary. After 1890, transverse systems were recommended in the European literature on the grounds of their supposedly greater draining capacity or

A study of the effect of tile direction on drainage capacity in sloping fields

"better" operation (9, 13, 14, 19, 20, 23, 25, 26, 31). The American literature (2, 8, 21, 22, 28) with a few exceptions (10, 12) remained in favor of the longitudinal system. In some of the most recent American drainage literature (1, 24) the problem of transverse or longitudinal drainage as such is not mentioned any more. Instead, recommendations are given for maximum and minimum tile grades.

Although the arguments used by several authors to demonstrate the greater draining capacity of one or the other system are subject to severe objections, it was felt that the difference between ground-water flow patterns of the two systems could result in a difference in draining capacity. For this reason the study was initiated.

Approach to the Problem

In the course of this investigation, distinction has been made between two cases. In the first case, the phreatic surface coincided over the entire field with the surface of the ground (surface runoff impending or already developed). The boundary conditions in this case were fixed and identical, whether the drainage system was longitudinal or transverse. In the second case, the soil was not saturated to the surface and the phreatic surface could seek its own shape. The shape of the phreatic surface in a transversely drained field differed from that in a longitudinally drained field.

Since capillary action was absent in the first case, this case was suited to a model study. The second case was approached mathematically. Field studies were not considered feasible because of difficulty of controlling the many variables, and the high cost involved.

The Model Study

The model consisted of a heavy wooden box, 5 ft square and 18 in deep. Drains were constructed from 80-mesh stainless steel wire cloth. A fine uniform sand formed the porous medium. The scale of the model was 1:30 and field spacings of 36 ft, 72 ft and 144 ft at a field tile depth of 3 ft could be represented. Keeping the depth of the drains in the model constant, the distance of the bottom of the box (i.e., impermeable layer) below the drains could be varied. The model could be tilted by various degrees in a direction normal to the drains (transverse drainage) and parallel with the drains (longitudinal drainage). A thin sheet of water running continuously over the surface was used to approach a phreatic surface coinciding with the ground surface. The sand was protected from erosion by three layers of cheese cloth underlying a stainless steel screen.

Inasmuch as the walls of the model normal to the direction in which the box was tilted did not coincide with natural stream surfaces, the flow pattern was disturbed, especially in the case of longitudinal drainage. To minimize the influence of this disturbance on the results, the drains

were divided into three sections and the discharges only measured from the middle section.

Results of Model Studies

The results obtained from the model study were expressed as the ratio of the drainage capacity of the transverse system to the drainage capacity of the corresponding longitudinal system, symbolized by Rtl .

Values of Rtl were determined at slopes of 5, 10 and 15 percent for different drain spacings and depths of the impermeable layer. Rtl appeared to scatter around 1.00 with values between 0.96 and 1.03. No relation existed between Rtl and the factors that control the flow conditions (depth and spacings of drains, depth of impervious layer, and field slope).

Computations showed that a consistent decrease in Rtl of about 1 percent for each increase of slope of 5 percent was introduced by the fact that the longitudinal drains had about the same slope as the tilt of the box, while the transverse lines kept nearly the same slope with which they were installed regardless of the tilt of the box. Thus the flow depth in the drains was less in the longitudinal systems, particularly at the greater slopes.

Since the surface of the sand could not be made perfectly flat, the thickness of the runoff sheet at a particular location may have varied with the direction in which the model was tilted, thus influencing Rtl .

The depths of the impervious layer below the drains included in the tests ranged from zero to one-fifth of the drain spacing. With regard to influence on drainage, the latter depth of the impervious layer can be considered as being infinite (15, 29).

Calculation of Rtl

In tile-drained sloping fields a ground-water particle moves under the combined influence of the tile and of the slope of the water table as introduced by the slope of the field. Moreover, the velocity potential due to tile lies in a direction normal to the tile, whereas the velocity potential due to slope lies in a direction normal to the contours.

Since, in a longitudinal system, the tile lines also run normal to the contours, the velocity potential due to the slope is normal to the velocity potential due to the tile. When the resultant of these potentials is resolved into com-

ponents, that component normal to the tile, which controls the flow of water into the tile, is identical to the velocity potential due to tile. In other words, slope does not affect the draining capacity of longitudinal systems, or longitudinal systems have the same draining capacity as identical systems in horizontal fields under otherwise the same conditions. The same thought is underlying Waring's recommendation of longitudinal systems (34), although not so stated specifically. This characteristic, which also appears from the results of the model study, reduces the comparison between longitudinal and transverse systems to that between horizontal and transverse systems. (With horizontal systems are meant drainage systems in horizontal fields.)

Tile-drainage systems in horizontal fields with uniform soils can be characterized by the following dimensionless quantities (given a certain tile diameter): x/m , d/m and k/s (Fig. 1), where

x =one-half of the tile spacing

m =vertical distance of water table at middistance between the tiles above the tile

d =distance of the impervious layer below the tile

k =permeability of the soil (dimension length/time)

s =drainage coefficient (dimension length/time)

The quantities x/m and d/m describe the geometry of the system, whereas k/s represents the reciprocal of the drainage coefficient at unit permeability. Nomographs constructed by relaxation processes relate k/s to x/m and d/m (33). If the impervious layer is at great depth, x/m is the only controlling factor of k/s . Consequently deep drains with wide spacings and shallow drains with narrow spacings have the same draining capacity as long as their x/m values are the same.

Fig. 2 shows a cross section of a transversely drained sloping field, with uniform infiltration (arrows equally spaced). The uniformity of infiltration causes the water table to attain such a shape and elevation that at steady conditions

$$\frac{x_1}{m_1} = \frac{x_2}{m_2} \quad \dots \quad [1]$$

In other words, a transverse tile line acts at its uphill side as a deep, widely spaced drain and at its downhill side as a

Fig. 1 Flow system in a tile-drained horizontal field

Fig. 2 Flow system in a transversely drained sloping field

shallow, narrowly spaced drain. The k/s values corresponding to the x/m values of the system can be found with the nomographs (33). From Fig. 2 appears

$$m_1 = m_2 + L_h \tan \alpha \quad [2]$$

and

$$L_h = x_1 + x_2 \quad [3]$$

From equations [1], [2] and [3], the following expression for L_h can be derived

$$L_h = x_2 \frac{2}{1 - \frac{x_2}{m_2} \tan \alpha} \quad [4]$$

The next step is to evaluate the drain depth D for the transverse system.

The minimum permissible distance p of the water table below soil surface (Figs. 1 and 2), together with the drainage coefficient s of the system at the position of the

(27), Debaube (7) and Van Schilfgaard (30). Finally k/s values were evaluated from the nomographs for horizontal systems with the same tile depths and spacings as were found for the transverse systems, and Rtl computed.

Summarizing, the calculation of Rtl for free boundary development consists of the following steps:

- 1 Starting with transverse systems, assume a range of values for x/m .
- 2 Using the nomographs, find the k/s values corresponding to the assumed x/m values.
- 3 Calculate L_h for the transverse system with equation [4] for the assumed x/m values at different field slopes. Computations are facilitated by assigning a concrete value to m_2 , thus giving the system a certain scale.
- 4 Using both theoretical and empirical shapes of phreatic surfaces, evaluate D for a given value of p .
- 5 Using the same value of p , find k/s for horizontal systems having the same depths and spacings as found for the transverse systems.
- 6 Calculate Rtl as

$$Rtl = \frac{(k/s) \text{ horizontal}}{(k/s) \text{ transverse}}$$

The results of these computations show that the values of Rtl are scattered around 1.00 (Table 1) with no relation to x/m and a slight tendency to increase with increasing slope.

Discussion of Results

Theoretically, the nature of the problem should not permit Rtl to scatter around a certain value. There is either a clear relation between Rtl and the factors that determine the geometry of the system or there is no relation at all.

Two quantities should have an undisputed influence on the deviation of Rtl from one if this deviation were to exist: the slope of the field and the spacing of the drains. The slope of the field may be considered as being responsible for the existence of the two different drainage systems. If the slope of the field were zero, there would be no question of direction of tiles with respect to contours because there would be no contours. Consequently, any difference between longitudinal and transverse systems should clearly bear the influence of field slope. The influence of the tile spacing becomes clear in the case of a zero spacing. If the tile lines lie right next to each other, it does not make any difference what direction these lines have with respect to the contours. A difference may start to develop, however, if the lines are moved apart.

The depth of the impervious layer and the position of the water table characterized by m , merely control the type of flow (radial or uniform rectilinear) that dominates in a given system. The model studies indicated that both for small values of d with rectilinear flow dominating and for large values of d with radial flow dominating, Rtl was equal to one. Consequently, the depth of the impervious layer is not important as far as Rtl is concerned.

The graphical evaluation of the tile depth in transverse systems with free boundary development was very sensitive to small changes in degree and location of curvature of the phreatic surface. Since the shapes of the curves used in this

water table characterized by p , constitute the drainage criterion on which the design of a drainage system should be based (15). On the other hand, it is possible to characterize existing drainage systems by their draining capacity at the position of the water table characterized by p . For horizontal systems, p is found at middistance between the tiles (Fig. 1) and the tile depth D is found by adding m to p . In the case of transverse systems, however, p is found at point T where a line having the same slope as the field is tangent to the phreatic surface (Fig. 2). To determine the location of point T , it is necessary to know the shape of the phreatic surface. Inasmuch as it has not been possible to develop simple equations that describe phreatic surface shapes, the tile depth for transverse systems was determined graphically. For this purpose a set of water table shapes with different x/m values was obtained by interpolation from theoretical curves presented by Childs (4, 5), Kirkham and Gaskell (17) and Van Deemter (29). A similar set was constructed from empirical curves presented by Spottle *et al.*

process may easily have been affected with some deviation from the true shapes, not too much value can be attached to the slight tendency of R/l to increase with increasing slope.

Based on the scattering of R/l around one and the absence of clear influences of the factors controlling the flow system, the conclusion is that both for fixed and free boundaries, no difference exists between the draining capacities of comparable longitudinal and transverse tile-drainage systems.

Summary and Conclusions

Transverse and longitudinal tile-drainage systems in uniform soils have been compared with regard to their draining capacities. In the drainage literature, different opinions about this subject are found, and contradictory recommendations for the proper direction of tile lines with respect to field contours have been made.

In the course of this investigation, distinction has been made between two cases. The first case, where the phreatic surface coincided over the entire field with the ground surface, was studied by means of a model. The second case, where the soil was not saturated to the surface and the flow system could seek its own phreatic surface, was approached mathematically.

The results showed that for both cases comparable longitudinal and transverse tile-drainage systems have the same draining capacities. On the basis of this result, it is recommended that tile lines (laterals) be installed at an angle between 10 and 30 deg with the contour lines. The lower limit of 10 deg is merely to indicate the practical undesirability of a tile parallel with the contours. The advantages of the recommended direction are:

- The main can be installed with a steeper grade than the laterals. This reduces sedimentation and allows a smaller diameter for the main.
- By letting the tiles diverge slightly from the contours the grades are sufficient that installation is not difficult.
- Although diverging somewhat from the contours, the laterals still have an effective direction with respect to surface runoff (27), to remnants of old streambeds, and to other natural drains (old stone drains).
- A reasonable divergence of the tile from the contours still takes advantage of a possible development of anisotropy in the soil with the greatest permeability in the downhill direction due to a repeated downhill movement of ground-water during the past (6). More research, however, is needed concerning this point.

RESEARCH NOTES

Brief news notes and reports on research activities of special agricultural-engineering interest are invited for publication under this heading. These may include announcements of new projects, concise progress reports giving new and timely data, etc. Address: Editor, AGRICULTURAL ENGINEERING, St. Joseph, Michigan.

USDA Research Activities

Superior Service Awards. Three ASAE members, on the staff of USDA's Agricultural Engineering Research Branch, ARS, received USDA Superior Service Awards at the honor award ceremonies held June 1, at the Sylvan Theater, Washington Monument Grounds, Washington, D. C.

The awards, presented by Secretary of Agriculture Ezra Taft Benson, were made to Jordan H. Levin and Harold P. Gaston of the Mechanical Preparation and Conditioning Section, AERB, for their research efforts at Michigan State College, on means and methods of handling fruit, and to Elmer B. Hudspeth Jr., of the Farm Machinery Section, for his work in connection with cotton mechanization at Lubbock, Tex.

Silo Research Continued. Experimental horizontal silos, constructed last year by the Farm Buildings Section of the AERB at Agricultural Research Center, Beltsville, Md., have been refilled for further tests of silage quality, means of covering, filling operations and pressures. The work will also include feeding tests and pasture station studies making use of a portable electric fence, to be conducted later by the Dairy Research Branch of ARS.

One of the silos was filled with chopped forage and the other with long grass, making possible the testing of new forage harvesters and tractor-mounted buckrakes by engineers of the Farm Electrification Section and the Farm Machinery Section. New pressure panels installed recently by engineers of the Farm Buildings Section are expected to give more accurate results of silo pressure studies than those previously obtained.

Cattle Shelter Handbook. A new illustrated handbook, "Cattle Shelters and Equipment for Southern States" (No. 81) has been prepared and issued by AERB. The plans shown in the handbook are available to farmers in the southern region through state agricultural extension services.

Included in the handbook are sketches of pole barns of various types, cattle pens, chutes and handling equipment for the farm. These depict plans developed cooperatively by USDA and the state colleges in 13 southern states as a result of farm buildings research.

Working drawings listed in the publication may be obtained from county agents or from the extension agricultural engineer at state agricultural colleges in the southern region. They are not distributed by the U.S. Department of Agriculture.

Radiofrequency Treatments. Strawberry plants are being treated by radiofrequency by S. O. Nelson, Farm Electrification engineer stationed at the University of Nebraska, as a means of controlling the virus diseases that cause yellows and crinkle. Plants under test have survived the treatment, but it is still too early to determine effect of the treatment on the viruses.

The Farm Electrification Section reports some success in the dielectric treatment of small grain for smut. Good results were obtained under the first test as compared with the untreated check.

Annual Report of the Secretary for 1954-55

To the Council and Members of the American Society of Agricultural Engineers:

A forward look has been chosen as the theme of the Secretary's report this year. As a major objective, the report will attempt to evaluate past and present society activities as a basis for intelligent projection.

On the horizon there appears an increasingly bright future for our profession—a future of increased opportunity for engineering services to the agricultural industry. The number of production units in agriculture will likely continue to decrease with increased production per unit. At higher levels of output engineering applications become increasingly profitable.

Greater engineering emphasis will be given to the reduction of chore time and increased efficiency of operations in and near farm buildings. This will be concurrent with further advances in the mechanization of field operations. The agricultural engineer will attack with increased vigor such areas as fruit and berry harvesting; transplanting operations; increased use of electronics in grading operations and in the maintenance of product quality, animal, plant and product environmental studies; and the engineering implications associated with scores of other problems in all segments of agriculture.

It behooves the Society to point the way in these and all new agricultural engineering developments. Never should satisfaction be gained from simply being abreast of progress; ASAE should serve to inspire agricultural engineers to produce at their maximum rates and to make their greatest contributions to the progress of the profession. Our Society can be this source of stimulation only as individual members contribute to its progress and welfare through suggestions and active participation in its affairs.

To the extent this is achieved agricultural engineers will consider membership in the Society to be a basic necessity for their professional progress. Enthusiasm of members will prove contagious, resulting in the most effective solution to the problem of society growth.

Growth. Growth of the Society will, as in the past, continue in two directions. Great potential still exists in those areas now generally recognized as being parts of the agricultural engineering profession. Outside of the Society are many engineers providing a service to agriculture through farm equipment manufacturers and distributors, public utilities, state colleges and universities, agricultural and engineering experiment stations, agricultural extension services, and various units of the United States Department of Agriculture.

The Society can grow in a broadening direction by gaining the membership of those engaged in areas near the present boundaries of the agricultural engineering profession. For example, prospective members may be found among those engaged in such diverse fields as engineering appraisal, private practice, design and development of specialized equipment, production and/or processing of various agricultural commodities, farm management, land development, agricultural aviation, wholesale and retail sales, farm safety, contracting, publications, advertising and sanitation. Agencies, both public and private, having a primary interest in the modernization of agriculture are good sources of prospective members.

This second direction merits considerable thought and work toward a sound policy as to how far and how fast the ASAE can

proceed and the manner and extent to which it can attempt to serve as an effective organizational mechanism for a wide diversity of technical and professional interests.

Growth should not, of course, be taken as the sole measure in determining the effectiveness of the Society in serving its members and the profession of agricultural engineering. It is nevertheless a very important indicator of the Society's vitality and vigor and the determination of its members to keep the Society an organization constantly pressing for a more effective engineering service to agriculture. Growth is an essential ingredient in any forward-looking organization.

Most, if not all, society members have heard of the slogan "5000 Members in '55" developed in conjunction with the drive for new members currently in progress. President Nutt emphasized the importance of the drive in his letter to the society membership dated May 10. With a view of reaching the goal of 5000 members in 1955, the Secretary's office is laying particular stress on increased membership. Contacts with agricultural engineering department heads, divisional and sectional officers along with as many additional personal contacts as possible have been fairly effective in progress to this time. As this is written (mid-May), the society membership numbers 4407, as compared with 4187 reported in the Secretary's report of last year. In addition 172 applicants are currently in the process of election to membership. Considering only members in good financial standing, the drive began approximately four and one-half months ago with a few less than 4200. The present membership plus those in process of election indicates a total gain since January 1 of 382 members. If the present rate of gain can be maintained, the goal of 5000 members on December 31 should be realized provided applicants in process of election to membership are considered in the total membership figure.

The new members gained and to be gained by the present membership drive will, of course, mean much to the Society. Of at least equal importance, however, is the hope that the present emphasis on membership will awaken in members a new sense of individual responsibility for the continued growth and effectiveness of their professional engineering society.

There are, of course, many problems associated with growth. For example, a forward look demands an answer to the question of how to make new members feel at home in the Society or, better perhaps, how to quickly and effectively incorporate their abilities into society affairs. Most of the members who resign or drop out do so after three to seven years of membership during which time they may have attended few, if any, sectional or national meetings. Their location or work may have given them few contacts with other agricultural engineers and little identification or recognition in their chosen professional field. In such contacts as they have had with the Society, they may have found no group or committee actively working along lines of their particular interests. Perhaps they have not felt well enough acquainted in the Society or familiar enough with the mechanics of its operation to try to find out which other members might have similar technical and professional interests, and to start some activity along those lines.

Educational institutions can be of great assistance in properly indoctrinating the

young engineer with his need for contacts and ingredients of professional progress normally supplied by his professional engineering society. Continuation of this indoctrination by aggressive employers would prove of great benefit. Yet despite the importance of these aids, the problem remains a real one in a forward-look at our Society and its work.

A further problem of growth is the fact that the Society has to lift itself by its own bootstraps financially. Desirable activities which would strengthen the Society can be placed in operation only as increased financial means become available, and this often-times centers about the necessity for increased membership.

Meetings and Organization. The future will undoubtedly hold major changes in the present make-up, organization and scheduling of our national meetings. Meetings of the technical divisions at widely separated geographical locations may well become part of the Society's meeting plan. Joint programs between divisions will have increasing appeal, particularly as the technology of our profession is brought to bear on the development of over-all production plans for agricultural units. Divisional and joint divisional programs sponsored by sectional organizations seem to be in the offing. Although it is only natural that considerable inertia and resistance to change have been built into the present generally satisfactory meeting schedule, it is not wise to consider it inflexible or unyielding to the interests and desires of large segments of the Society's membership.

A forward look at committee activities within the Society indicates that this type of work will continue and increase in importance. A greater emphasis will be placed on clarifying and pin pointing problems along with the development of procedures for their solution. Division committees will be increasingly controlled by well-organized steering committees who will insist that the committee's work be directed toward the accomplishment of clearly stated, reasonable objectives. Target dates for completion of the committee's assignment or specific parts of the assignment will be established. Divisional steering committees will be called upon to a greater extent to collaborate with the Secretary in suggesting to the President suitable individuals for committee appointments, in reviewing at least annually the status of the committee's work and in analyzing and taking appropriate action on committee reports.

This same line of reasoning should be applied to the divisional organizations. As technical emphasis shifts, based on technological progress, divisional organizations should reflect these changes. It is not outside the realm of possibility that the present divisions might at some future time see fit to merge, a single division divide, and other major changes take place toward making the organization of the Society better suited to serve the professional needs of its members.

Every indication points to the continued growth and effectiveness of our sectional organizations as one of the most important means of the Society carrying out its objectives. Few, if any, would dispute the fact that the service rendered by the sections has exceeded even the greatest hope of their organizers. They form a solid foundation on which to an increasing extent the hopes and aims and ambitions of the Society are based. Servicing and the encouragement of these sectional organizations will become an increasingly important function of the headquarters operation.

Student Recruitment. The Society will carry its share of responsibility in the work of the engineering profession to acquaint American youth with their responsibilities and opportunities to produce to the full limits of their ability in a free society. The Society will encourage accurate presentations of the opportunities and responsibilities of professional engineering as illustrated by the education and ability of the agricultural engineer. This activity of accurately presenting agricultural engineering as a vocation to qualified high school youth will command the interest of all organizational elements in the Society—headquarters, sections, divisions, and committees. Problems incident to student recruitment will be solved not by defeatist attitudes but through hard work, sound factual approaches, and in general by a program having greater appeal than those presented by professions and vocations with which agricultural engineering is in competition for prospective students. The present motion picture program is a splendid example of effort properly directed to achieve this goal.

The future holds greater team work between agricultural engineering departments and the Society in indoctrinating agricultural engineering students with a professional consciousness. Student branch organizations and the Student Member program will be of increasing concern to all elements of the Society.

Public Relations. In looking ahead one must appreciate the importance of the continued development of a sound public relations program. This must go considerably beyond effective coverage of our national and sectional meetings. Agricultural engineers in common with engineers in other branches must become more proficient in telling others of their work. Members of the Society wherever they may be located can be of great assistance in acquainting the Secretary with opportunities to make the profession better known. Channels are available for the dissemination of information if story opportunities are known and properly exploited. Through the interest of individual members or small groups of members the following projects, now under way, are valuable parts of the over-all public relations program now in operation in the Society:

- 1 Motion picture depicting the agricultural engineering profession which was the subject of a general mailing in April.
- 2 An article dealing with the Society and the development of the agricultural engineering profession is scheduled for publication in the July issue of the *General Electric Review*. This article is one of a series featuring the history and activities of professional engineering societies in the United States.
- 3 The Society has accepted an invitation to have a booth among the educational exhibits at the Centennial of Farm Mechanization to be held at Michigan State College in August. The exhibit will emphasize the professional stimulation which agricultural engineers receive from working together in their own professional engineering organization.
- 4 Information on the Society's activities in the field of standardization has been provided the National Industrial Conference Board as a contribution to a study it is making in cooperation with the Mellon Institute on the present significance and use of industrial standardization.

- 5 At the invitation of the Trade Association Division of the United States Department of Commerce, information on the Society has been supplied for inclusion in a section on professional engineering societies to be included in the new directory of trade associations being published by the Department.

- 6 At the invitation of the American Society of Mechanical Engineers the ASAE was officially represented at the organization anniversary meeting of that society held at the Stevens Institute of Technology, Hoboken, New Jersey, on April 16. President Nutt designated Mr. L. H. Skromme, senior vice-president of the Society, as the official ASAE representative. This meeting was part of the ASME diamond jubilee celebration. Official greetings were extended by Mr. Skromme from the current and first president of the American Society of Agricultural Engineers, Professor George B. Nutt and Dr. J. B. Davidson, respectively.

- 7 The Society had official representation at the golden anniversary meeting of the Society of Automotive Engineers held in Detroit, Michigan, on January 12.

- 8 The agricultural engineering profession will be appropriately covered in future yearbooks and revisions of the *Encyclopedia Britannica*.

Suggestions are solicited from members relative to the continued expansion and increased effectiveness of the Society's public relations program.

To an increasing extent the Society will be active among those organizations having as a goal the over-all advancement of the engineering profession. Affiliation and cooperation with other professional and scientific groups will continue at an accelerated pace. The Council wisely recognizes this as essential to the continued effectiveness of the Society in serving the profession and its members.

The President. A very important part of the progress which the Society has made during the past year centers about the fine work of our President, Professor George B. Nutt. His actions have not only been well considered and wise but his leadership aggressive and dynamic. His duties as president have been discharged in a manner as to bring credit not only to himself but to the Society and agricultural engineers everywhere.

Headquarters. The forward look materialized in the matter of headquarters location between the time this report was started and its completion. Moving day came at a time when arrangements for the annual meeting had peaked the headquarters work load, but the action was necessary if advantage was to be taken of a more favorable location for our operation. The headquarters now occupies the first floor of the Masonic Temple, 420 Main Street, in St. Joseph. Main Street at our location forms highway routes US 12 and 31. You are cordially invited to visit us whenever you pass this way.

The headquarters staff consists of nine full-time and two part-time employees. As evidenced in the recent move, the staff has the splendid ability to act as a unit in the interests of the Society. During the coming year it is hoped that many of the routine headquarters functions can be studied, streamlined, and incorporated into a standard operating procedure. A forward look includes more complete up-to-date and

meaningful membership records, a policy guide for councilors, a guidance manual for student branches and Student Members, a study of past, present, and potential services of ASAE members in the national defense, expansion of the Personnel Service—these are but a few of our aims and ambitions.

Those of us at headquarters feel a genuine concern for your professional development

and welfare. Only through the maximum development of its individual members can our Society grow and render its greatest service to the advancement of the agricultural engineering profession.

Respectfully submitted,

FRANK B. LANHAM, *Secretary*

June 14, 1955

Annual Report of the Publisher for 1954-55

To the Council and Members of the American Society of Agricultural Engineers:

A primary object of the Society, as stated in its Constitution, is "to promote the science and art of engineering in agriculture." One means to this end is the publication of the body of information that is considered an essential tool of the members in their work as agricultural engineers.

The American Society of Agricultural Engineers in common with other technical societies early found it necessary to provide its own publishing facilities, to insure more adequate means of making the literature originating from its activities available to members and others in need of it. Probably no society, however, representing a rapidly expanding profession, is today finding it possible to supply means of publication as fully as needed. This is one of the most perplexing problems now confronting technical societies. However, there are indications that a concerted effort may eventually be made toward finding a solution; the pressing needs of these times for stepping up scientific and technical advancement may well result sooner or later in definite steps toward assisting the societies with their publishing problems.

What is being done—and what more needs to be done—in our organization, to meet our particular publication requirements?

AGRICULTURAL ENGINEERING was established in 1920 to provide more adequate publication of our reference literature than was then possible with the annual "Transactions," but the growing volume of papers presented at national and section meetings of the Society—and including special articles prepared expressly for the Journal—has long since exceeded our facilities. Journal space now being devoted to technical material consists mainly of those meeting papers and special articles that are considered as having the greatest value to the most members as reference literature. That is not to say, however, that we are printing *all* papers that merit publication. The combination of an increasing amount of material and higher publishing costs presents the Society with an exceedingly difficult problem, the solution to which is still to be found.

Since it is not feasible to increase the size (number of pages) of AGRICULTURAL ENGINEERING beyond certain limits, consideration needs to be given to other forms of publication of meeting papers, committee reports, etc., not used in the Journal but which are important sources of new information needed by our members. Since much of this material has more or less temporary value for reference use, copies supplied in mimeograph or other forms of duplicating would doubtless meet most requirements. There is, however, an increasing number of papers, usually quite technical, that are useful for reference to a relatively small percentage of members. Such material could be supplied in the form of printed separates or in a revived "Transactions" published annually or at more frequent intervals.

The Divisions of the Society, specially

their technical committees, along with the everyday technical problems confronting them as agricultural engineers, might well give more attention to our publications problem, for it is primarily a group problem and one that concerns every group in ASAE, large or small. The fund of technical literature, together with the combined experience of individual agricultural engineers, is what constitutes the working capital of our profession. Your contributions to the fund need to be preserved and made conveniently accessible so that all may draw on it.

The extent to which the number of pages in the Journal can be increased to provide more space for papers depends largely on the amount of advertising space scheduled. We aim to have reading matter and advertising apportioned about fifty-fifty. The proportion of space devoted to technical papers could be considerably increased were it not for the fact that we lean heavily on the Journal to help finance other than the strictly publishing activities of the Society. The Journal, therefore, must be published at a profit.

* * *

The choice of papers for use in AGRICULTURAL ENGINEERING is a responsibility which appropriate committees or groups of the Society should share with the editor, in order that a more adequate evaluation may be made of the material available for publication. As a means to this end, the proposed procedure appended to this report, for consideration of publishable material, was submitted last November to the Council and Division Executive Committees of the Society. This proposal is aimed primarily at providing more satisfactory selection of papers worthy of publication. It is believed to be a workable solution of this problem, and it is recommended that the Divisions and Sections proceed with implementing the plan.

* * *

The issuing of AGRICULTURAL ENGINEERS YEARBOOK begun a year ago has provided a much needed means for publishing a variety of information required by our members, and it appears to have been a timely and useful addition to our publishing activity. Perhaps its greatest advantage is in the convenience of having the material under one cover.

Just how permanent the Yearbook may prove in its present form and content is something that can be determined with a few years experience. The 1955 edition is 32 pages larger than the first (1954) edition, and with future editions becoming still larger, as we anticipate, the publication in time may become too bulky for practical use. However, when this point is reached, it is believed the contents can readily be divided into two separate publications and still be about as convenient and practical as in the present form.

* * *

Since AGRICULTURAL ENGINEERING was established, the aim has been to make it an increasingly profitable business publication as well as a technical journal, serving ASAE members, and the record since shows that

this purpose has been achieved to a gratifying extent, though not yet as fully as will eventually be realized. As a result of its 35 years of publication, AGRICULTURAL ENGINEERING has gained general acceptance as a respected technical journal of which we can be justifiably proud. Its acceptance as an advertising medium by advertisers and advertising agencies has been most gratifying and is our assurance that continued progress in making it a more profitable publishing property can reasonably be expected.

Each year AGRICULTURAL ENGINEERING has been consistently showing increases in the amount of advertising carried, and 1954 was no exception though early in the year non-renewal of several of our best schedules made the outlook for another record-breaking year anything but promising. As it turned out, sufficient new schedules were obtained to offset the non-renewals.

Our purpose is to continue to improve AGRICULTURAL ENGINEERING as a profitable advertising medium, as well as a technical journal, because we consider it our best source of revenue for improving and expanding our over-all publication facilities.

AGRICULTURAL ENGINEERS YEARBOOK is still too new as a publishing venture to evaluate its possibilities as an advertising medium. Space sales in the 1955 edition exceeded those of the 1954 edition by 15 percent which is a gratifying increase. We expect the sale of advertising space to increase from year to year, and if the return from space sales is eventually sufficient to offset cost of publication, we will consider it quite an achievement.

The American Society of Agricultural Engineers is definitely in the publishing business, with all that the term implies, including greater opportunity (1) for serving the needs of its members for technical literature and other professional information and (2) for developing publications as producers of revenue to make them at least self-supporting. I am convinced these properties have promising potentialities for expansion.

Respectfully submitted

RAYMOND OLNEY, *Publisher*

June 14, 1955

Recommended Procedure for Considering Technical Papers for Publication in Agricultural Engineering

Technical manuscripts available for publication in AGRICULTURAL ENGINEERING derive mainly from four sources:

- Papers presented on Division-sponsored programs at ASAE national meetings
- Papers presented on meeting programs of ASAE Sections
- Papers, reports, data contributed and approved by ASAE Committees
- Original articles authored by ASAE members and others.

Consideration of manuscripts intended for use in AGRICULTURAL ENGINEERING involves three stages:

- *Evaluating* papers or articles from the standpoint of contributing timely new information of value to the expanding literature of the profession
- *Recommending* such improvement in publishable material as is necessary to enhance its value for reference use
- *Scheduling* of approved material for publication.

The *scheduling* of approved manuscripts for publication is largely a routine editorial function, in which several factors, such as demand, timeliness, variety of subject matter, space requirements, etc., have to be duly considered. The main problem confronting the Editor—and one that explains the primary purpose of the procedure herein outlined—is need of the advice of experts (authoritative specialists):

(1) in *evaluating* individual manuscripts for publication and (2) in *recommending* also such improvement — revising, condensing, etc. — as may be needed to facilitate their use for general information or technical reference.

The most logical approach to a solution of the problem seems to lie in setting up special committees—"Papers Committees"—to take responsibility for directing the work of carefully appraising papers, articles, etc., and making recommendations pertinent to their publication in most useful form. The form of organization presented in the following paragraphs is recommended:

Division Papers Committees. It is recommended that each Division Executive Committee, possibly with the advice of the Division Steering Committee, form a "Division Papers Committee." The function of this committee is to provide the Editor with expert advice — given by its own members and/or other competent individuals — on papers and articles considered for publication in *AGRICULTURAL ENGINEERING*. The nature of such advice should be twofold (namely: (1) evaluate material available for publication and (2) suggest revisions that would enhance its value to readers.

Following ASAE annual and winter meetings, Division Papers Committees will be asked to appraise papers presented on programs arranged by their respective Divisions and report their opinions and recommendations concerning publication to the Editor.

In addition to papers presented on Division-sponsored programs, each Division Papers Committee will be asked to give similar counsel concerning the following publishable material, that is, within its subject-matter scope:

- Papers presented on ASAE Section meeting programs
- Contributions on ASAE technical committees
- Original articles by ASAE members and other authors.

Section Papers Committees. It is recommended that the Executive Committee of each ASAE Section be asked to form a "Section Papers Committee," the function of which would be (1) to consider the suitability for publication of *technical* papers presented on Section meeting programs and (2) to see that manuscripts of papers deemed worthy are submitted to the proper Division Papers Committees for further appraisal and recommendation concerning publication. (Non-technical papers and addresses before Section meetings could be submitted direct to the Editor by the Section Papers Committee.)

Personnel of Papers Committees. Each Division or Section "Papers Committee," as contemplated by this procedure, would function *primarily* as a "clearinghouse" and *secondarily* as a body of experts or authoritative specialists. For that reason the clearinghouse function may be facilitated if the personnel of each Papers Committee includes part or all of the members of the Division Executive and/or Steering Committees and of the Section Executive Committees.

The constituting of a "body of experts" to be members of or advisory to a Division Papers Committee, is likely to include Society members other than, and in addition to, those serving on the Executive and Steering Committees.

Latitude of Editor. Since the activity of Papers Committees will be carried on largely by correspondence, the procedure herein outlined may prove somewhat cumbersome, resulting in more or less delay in getting manuscripts approved and made ready in suitable form for publication. It is therefore understood that the Editor will exercise whatever latitude may be necessary in the selection and use of publishable material — prior to formal approval by Papers Committees — so as not to handicap monthly publication of the Journal.

Our publications possess considerable potential for increasing Society income. The past record of the Journal proves this. However, it is believed the interests of our members will be best served if most of the net revenue from the publications is used to improve and expand their usefulness.

A third means — though never a popular one — of increasing Society income is to raise membership dues. Ordinarily this should not be done, except as a last resort. However, in the face of growing demands for such services as we would all like to see the Society provide its members, and recognizing that these demands are increasing out of proportion to the increase in income, we are right now facing the stern choice of raising dues or restricting services. Given a choice, it is believed members generally would find increasing the dues less objectionable. It is quite general knowledge that most engineering societies in recent years have been forced to make substantial increases in membership dues. To meet the apparent general demand from members for more service rather than less — and at the same time make sure that outgo does not exceed income — it is difficult to see how a dues increase can be avoided.

All three of the principal sources of Society income — membership dues, Journal subscriptions, and Journal advertising — produced increases in 1954 over the preceding year, the over-all increase being approximately 12 percent. Contributing also to this increase was an \$8,300+ item covering Yearbook advertising and copy sales.

Significant of the importance of the Journal in the financing of our Society activities is the fact that approximately one-half of our total income for 1954 was from the sale of advertising space. Add to this the credit for Journal subscription and copy sales and the record shows that the publication accounted for 64 percent of the total 1954 income.

The year 1954 broke another record for advertising sales in the Journal which was particularly gratifying, since the prospect at the beginning of 1954 was for a falling off in advertising during the year. The year closed with a \$2500 increase over the preceding year.

The first (1954) edition of *AGRICULTURAL ENGINEERS YEARBOOK* was published at a loss — that is, the net return from advertising space and from the sale of copies of the publication to non-members was not sufficient to offset the cost of printing and distribution. This was not unexpected, specially since it was a first edition. Our goal, however, which we have been successful in more than reaching in the case of *AGRICULTURAL ENGINEERING*, is to net a return from advertising and copy sales in excess of production and distribution costs.

Against a 12 percent increase in total receipts for 1954 over the preceding year, must be recorded an 18.5 increase in total disbursements. The auditor's report shows that the 1954 fiscal year closed with a net gain or profit of \$2,703.81. This is less than one-third of the profit for the preceding year, and emphasizes the point already made in this report, namely, that Society operating cost is fast overtaking income. Serious attention will need to be given to reversing this trend, but it is your treasurer's recommendation that this be accomplished, not by restricting the services of the Society to its members, but rather by developing ways and means of increasing income in order to *expand* our services.

Respectfully submitted

RAYMOND OLNEY, Treasurer
June 14, 1955

Annual Report of the Treasurer for 1954-55

To the Council and Members of the American Society of Agricultural Engineers:

The financial condition of the Society at the close of the fiscal year ending December 31, 1954, is shown by the Balance Sheet of Assets and Liabilities in the accompanying report of the auditor, Daniel W. Potter, CPA, of St. Joseph. (See page 408.) The report also covers total Society income and expense for the 12-month period.

Nothing portrays the growth of the Society as a business operation quite so vividly as the annual financial reports to the members, especially if a comparison of these reports from year to year is made. The Society business has been making substantial growth in recent years, and it is significant to note that in the 10 years since the close of World War II our annual income has almost tripled. Following is a tabulation of total receipts of income for each of the ten years, together with the percentage increase in each case over the preceding year:

1945—\$	52,500—20.6 percent
1946—	53,000—9.5
1947—	59,000—11.3
1948—	66,000—11.8
1949—	71,000—7.6
1950—	82,000—15.4
1951—	99,000—20.7
1952—	117,000—18.2
1953—	133,000—13.7
1954—	149,000—12.0

In this same 10-year period the cost of operating our business has also increased. Up to and including 1952, however, the rate of increase in operating cost was appreciably lower than the increase in income, and as a result we were able to build a fairly substantial cash reserve of approximately \$80,000, all of which is invested in United States Savings Bonds. The greater part of this reserve was accumulated in the 9-year

period, 1944-52, during which time in excess of \$67,000 in bonds were bought.

It needs to be pointed out, however, that during the past three years the margin between income and expense has begun to narrow perceptibly. With increases in personnel at our central office and growing demands for the services of the Society, the cost of operating our organization is now fast overtaking annual income.

To make certain that ASAE continues to maintain a sound financial condition, there is need to give early attention to ways and means of increasing our income to meet the larger expenditures called for by our expanding activities. It is certain that the members would not be in sympathy with operating our Society business on other than a balanced budget.

The stepping up of effort of recent months to increase new member enrollments is one means of adding to income, but it is the experience of organizations like ours that, unless high-pressure methods of membership enrollment are resorted to—and they are always highly questionable, to say the least — increasing income by adding new members is a relatively slow process.

Another step toward increasing income was taken January 1st when rates for advertising space in *AGRICULTURAL ENGINEERING* were increased approximately 18 percent. This action was in accord with usual publishing practice of raising advertising rates when warranted by gains in circulation and when required to meet upward trends in publishing costs.

Higher space rates for *AGRICULTURAL ENGINEERS YEARBOOK* were announced June 1st, and for the same reason. The new advertising rates on both Journal and Yearbook will not be in effect to any extent, however, until 1956.

Auditor's Report for 1954

To the Council of the
American Society of Agricultural Engineers:

I have gone over the books and records of your society for the year 1954 and attach the following schedules: Assets and Liabilities, Receipts and Disbursements, and Bank Proof.

No change has been made in the U.S. Savings Bonds account, except that eight (8) \$500 bonds falling due in late 1954 had been turned in for redemption, but the

St. Joseph, Michigan, March 19, 1955

funds were not received until after December 31, 1954. The investment in additional bonds during these years of high income could well be discussed at your next meeting.

Receipts show 12 percent increase over 1953 due mainly to an increase in membership dues and to Yearbook advertising sales.

Books and records were found to be in very good order.

(Signed) DANIEL W. POTTER, CPA

BALANCE SHEET — DECEMBER 31, 1954

ASSETS		
Current Assets:

NEW BOOKS

Agricultural Process Engineering, by S. M. Henderson and R. L. Perry. Cloth, ix + 402 pages, 5½ x 8½ inches. Illustrated and indexed. John Wiley and Sons, Inc. (440 Fourth Ave., New York 16, N. Y.) \$8.50.

This is the third book in publication in the Ferguson Foundation Agricultural Engineering Series of texts. It broadens the foundation for professional training of agricultural engineers in agricultural processing, previously supplied only in part by texts on dairy engineering and other specialized subjects and by material available only in scattered references. It should contribute materially to realization that engineering is involved in processing agricultural products on a commercial scale; to recognition that this is agricultural engineering when the operation is handled on or near farms and influenced by agricultural considerations; and to the development of agricultural processing on an economically sound basis. Chapters cover the engineering approach, fluid mechanics, fluid-flow measurements, pumps, fans, size reduction, cleaning and sorting, materials handling, heat transfer, air-vapor mixtures (the psychrometric chart), drying, refrigeration, process condition observations, records, and controls, cost analysis, process analysis and plant design, and manual operation economy.

Farm Shop Skills in Mechanized Agriculture, by Sampson, Mowery, and Kugler. Cloth, 395 pages, 5½ x 8½ inches. Illustrated and indexed. American Technical Society (848 East 58th St., Chicago 37, Ill.) \$4.95.

This new text and reference covers both the how and why of a wide range of farm shop, maintenance, repair, and minor construction jobs. Legends with illustrations outline steps in the jobs shown, to add to the reference value of the book. Chapters cover the farm shop, woodworking with hand tools, woodworking with power tools, painting of farm buildings and equipment, concrete and concrete masonry construction, soldering and pipe fitting, metal working on the farm, welding practices on the farm, fitting shop and farm tools, using electricity on the farm, maintaining farm machinery and farm shop projects.

Hydroponics: The Bengal System, by J. S. Douglas. Cloth xii + 147 pages, 5 x 7 inches. Illustrated and indexed. Oxford University Press, 114 Fifth Ave., New York 11, N. Y. \$1.60.

This is apparently a reprinting, not indicated as revised, of a book first published in 1951, in which the author explains a system of soilless plant culture which he devised, and which he advocates as a solution to India's food problem. Chapters include introduction, how plants grow, apparatus, nutrient mixtures, the system in practice, general technique, commercial possibilities, common deficiencies, miscellaneous notes, and the future of hydroponics.

Elements of Soil Conservation, by Hugh H. Bennett (Second edition). Cloth x + 358 pages, 6 x 9 inches. Illustrated and indexed. McGraw-Hill Book Co., Inc. (330 West 42nd St., New York 36, N. Y.) \$3.96.

This brings up to date an elementary non-technical text and reference on the subject for use at vocational and high school as well as college general training levels.

How **LINK-BELT CHAIN** *makes* *good farm machinery better*

1. EXPERT ENGINEERING AND FIELD TESTING. To build both high efficiency and long life into drives and conveyors, Link-Belt maintains an engineering staff of unequalled ability and experience. New developments are thoroughly field-tested.

2. LABORATORY CONTROL. Every chain bearing the Link-Belt trade mark meets rigid uniformity specifications. Our modern laboratory continuously explores new manufacturing refinements to increase chain life.

3. ACCURATE MANUFACTURE. In the world's largest chain plant—modern, specialized machines provide the economies of large-scale mass production, yet maintain high accuracy. Continuous inspection safeguards tolerances and finish of every length of chain.

4. COMPLETENESS ASSURES LOW-COST, PRACTICAL ANSWERS. With Link-Belt's broad line of chains and sprockets, farm machinery manufacturers are sure to get the *one* chain that's best for each application. Next time you're faced with a drive or conveying problem, look to Link-Belt's complete line. Call your nearest Link-Belt office for full information.

**"My Stainless Steel
bulk tank will pay for
itself in 3 years"**

— says Dairyman Robert S. Pike
Cornish, Me.

Milk from Mr. Pike's herd is piped directly into this 600-gallon Stainless Steel bulk tank from which it is picked up every other day. At peak periods the pick-up averages 550 gallons.

CURRENTLY milking a herd of 85 Registered Jerseys, Mr. Pike has been using the bulk milk handling system since June 1, 1954. His 600-gallon Stainless Steel farm tank has already made possible an impressive list of savings.

1. Hauling charges have been reduced 5 cents per cwt.
2. Losses through stickage and spillage have been eliminated.
3. Cleaning up takes only 15 minutes.

No more men are required to handle the herd which has more than doubled since can-handling days.

4. Butterfat count has improved one to two points.

These are the dollars-and-cents savings that Mr. Pike feels will make the Stainless tank pay for itself in 3 years. But don't overlook such other benefits as reduced bacteria count and the elimination of hard, physical labor.

Because of its economies, bulk milk handling with Stainless Steel farm tanks is one of the fastest growing trends in dairying today. It's an idea you'll want to be able to discuss with farmers in your area who are hearing about it.

For more information, mail the coupon below. United States Steel—as the producer of USS Stainless Steel from which bulk tanks are fabricated—has prepared a special booklet on bulk handling of milk. It's yours without obligation.

A report to you about the men and machines that help maintain International Harvester leadership

NEW 300% stronger track frames for INTERNATIONAL® CRAWLERS

**... provide the "muscle" to resist shocks and
stresses, cut operating cost!**

Super-strong, direct-attached deep tillage equipment imposes tremendous stresses on crawler track frames. Bulldozing often stops a crawler abruptly "in its tracks," piles up *high impact* shock loads.

International Harvester engineers have developed new track frames to meet and beat such tough applications, years on end. Track rollers are securely mounted in the new frames between two rigid box-section weldments. The box sections themselves are welded in parallel alignment with extra thick steel plate at the top reinforced with heavy-duty vertical steel gussets between the rollers.

Result: 300% stronger track frames! They're bridge-strong and machined to keep tracks aligned with greater-than-ever lifetime precision—to provide non-twisting support for true-running track rollers and idlers! International crawler owners get increased capacity and uninterrupted performance. Results: lower upkeep, greater profits!

This new big crawler McCormick® mounted tool bar carrier permits hard ground subsoiling, as deep as 32 inches.

The blade for the International TD-14A crawler's combination carrier gives the farmer big material-moving capacity.

International Harvester engineering teamwork produced the new International crawler track frames. International Harvester research, engineering and manufacturing men are constantly pooling their time and talent to provide equipment that makes work easier and the farmer's time more productive.

INTERNATIONAL HARVESTER

International Harvester products pay for themselves in use—McCormick Farm Equipment and Farmall Tractors . . . Motor Trucks . . . Crawler Tractors and Power Units . . . Refrigerators and Freezers—General Office, Chicago 1, Illinois.

NEWS SECTION

Stoddard Heads Alabama Section

LOWELL STODDARD, manager, Hanna Tractor Co., Birmingham, Ala., was elected the new chairman of the Alabama Section of the American Society of Agricultural Engineers at its regular spring meeting held at Dadeville, Ala., April 8 and 9. He succeeds F. A. Kummer, head of the agricultural engineering department, Alabama Polytechnic Institute.

The new vice-chairman of the Section is Lawrence Ennis, Jr., extension specialist in agricultural engineering, Alabama Polytechnic Institute. E. S. Renoll, assistant professor of agricultural engineering, API, is the new secretary of the Section. Hurst Mauldin, senior agricultural engineer, Alabama Power Co., was elected reporter of the Section.

The meeting opened on the afternoon of April 8 with a tour and demonstrations including a demonstration of surface irrigation and a tour of the Russell Manufacturing Company's plant. At the dinner in the evening the Section was addressed by Judge Jack Coley, who gave an interesting talk of the Indian battle at Horseshoe Bend. This was followed by a motion picture presented by Frank Lister of the Goodyear Tire and Rubber Company on the moving of materials and people by large conveyor belts.

The April 9 program featured three speakers and a panel of members of the Student Branch of ASAE at API. Interest-

ASAE Meetings Calendar

May 26—GEORGIA SECTION, Fleming, Ga.

June 3-5—TENNESSEE SECTION, Montgomery Bell State Park, Tenn.

June 12 to 15—48th ANNUAL MEETING, University of Illinois, Urbana

August 22-24—NORTH ATLANTIC SECTION, University of Connecticut, Storrs

December 12 to 14 — WINTER MEETING, Edgewater Beach Hotel, Chicago

NOTE: Information on the above meetings, including copies of programs, etc., will be sent on request to ASAE, St. Joseph, Mich.

ing observations of engineering and agriculture viewed by a magazine editor were presented by Harold Benford of *Progressive Farmer*. This was followed by a discussion of the new county agent demonstration program by J. L. Lawson, associate director of the Alabama Extension Service. The results of some recent feed grinding and mixing tests were discussed by J. L. Butt, associate agricultural engineer, Alabama Agricultural Experiment Station.

The panel discussion participated in by members of the local ASAE Student Branch covered some of the problems which the students considered serious from their standpoint, one of which was the lack of knowledge among high school students in the southern states of the profession of agricultural engineering.

Oklahoma Meeting

THE spring meeting of the Oklahoma Section of the American Society of Agricultural Engineers was held at Chickasha, April 15, with more than 50 ASAE members and friends present.

Harry W. Pitzer, vice-president, Public Service Company of Oklahoma, opened the program of the meeting with a talk on the agricultural engineer's place in Oklahoma agriculture. He was followed by James E. Garton of the Oklahoma A. & M. College agricultural engineering department who talked on irrigation with a limited water supply.

Following this program the group were given a field trip in the vicinity of Chickasha to inspect demonstrations and other points of special interest to agricultural engineers. At the cotton research station, E. W. Schroeder, head of the Oklahoma agricultural engineering department, and members of the staff gave demonstrations and reports on research work being done on cotton mechanization.

Roy E. Hayman, agricultural engineer, Public Service Company of Oklahoma, served as chairman of the local arrangements committee.

A-E Curriculum in the Philippines

THIS month the Central Luzon Agricultural College, Nueva Ecija, Philippines, will offer a professional curriculum in agricultural engineering. This will mean the implementation of the aim of the college as contained in an order by the President of the Philippines to "provide professional, technical, and special instruction for special purposes, promote research, extension service, and progressive leadership in agricultural education, agricultural engineering, home economics and other fields." This curriculum is designed to meet the growing demand for professionally trained and competent men needed in the country's agricultural development through the application of engineering principles.

ASAE Alabama Section is welcomed to Dadeville for its meeting April 8 and 9 by County Agent Fletcher Farrington

Pictured here are 47 of the 65 ASAE members and friends who registered attending at the spring meeting of the ASAE Pennsylvania Section held April 14 and 15 on the campus of Pennsylvania State University

NEW

Zinc-Coated Tubing Offers Full Rust Protection

Have you avoided welded steel tubing in designing your farm equipment because you couldn't get the rust protection of a zinc coating? Now you can obtain Armco Steel Tubing made of ZINCGRIP, the special zinc-coated steel that provides unbroken rust protection.

Armco ZINCGRIP Tubing is made from ZINCGRIP strip by the electric resistance welding process. Before emerging from the tube welding machine, the welding flash is planed from the tube and the zinc coating at the seam is replaced on the outside by a special metallizing process. The location of the welded and recoated seam can be found only by careful inspection—it's that smooth.

Available in Many Shapes. This zinc-coated tubing gives you an opportunity to make full use of the advantages of tubular parts in all kinds of farm equipment. It is supplied in rounds, squares, rectangular shapes, hexagons, octagons and special shapes, all with unbroken zinc coatings.

Rounds are produced in outside diameters from 5/8-inch

through 3 inches, and in wall thicknesses of 20 gage through 12 gage, depending on size.

Just fill in the coupon for complete information on Armco ZINCGRIP Tubing.

NEWS OF ASAE MEMBERS

Russell R. Raney has accepted appointment as director of engineering of the New Idea Division, Avco Manufacturing Corp., Coldwater, Ohio,

R. R. RANEY

having resigned as assistant manager of engineering of the farm implement division of International Harvester Co.

Mr. Raney is a 1934 mechanical engineering graduate of the University of Michigan. Upon graduation he accepted employment with International Harvester at its Auburn, N. Y., plant, and from there he was

transferred to the company's McCormick Works at Chicago in 1941. He was serving as chief engineer at the McCormick Works in 1952 when he was promoted to the company's general staff as a divisional chief engineer. Since early 1954 he has been responsible for all of the company's advanced farm equipment engineering.

Mr. Raney attended the executive program of the University of Chicago and earned his M.S. degree in business administration in 1948. In addition to membership in ASAE, he is a member of Beta Gamma Sigma, the American Society of Mechanical Engineers and American Farm Economic Association.

Austin R. Cline was recently released from active duty with the U.S. Marine Corps, and is now employed by Shell Chemical Corp. at San Francisco.

Harold M. Schudt was recently promoted from the position of assistant to the vice-president and director of engineering, Tractor Division, Allis-Chalmers Manufacturing Company, to that of president of Canadian Allis-Chalmers, Limited. From January 1948 to October 1954 Mr. Schudt was general manager of the company's Gadsden, Alabama Works.

H. M. SCHUDT

In his new capacity, Mr. Schudt will be in charge of operations which include general offices in Lachine, Quebec; manufacturing plants at Lachine and St. Thomas, Ontario, and sales offices in Montreal, Toronto, Winnipeg, Calgary and Vancouver.

Mr. Schudt started with the company in 1929 under an engineering cooperative program between the company and Marquette University. He graduated in 1932 with a mechanical engineering degree and in 1935 was transferred to the engineering department of the company's Tractor Division. In 1946 he was named a special representative for the Tractor Division's export department and spent two years in England where he started the company's first manufacturing operations at Southampton.

Wylie E. Corbett, who has been on duty with the USAF, has now returned to civilian status and is employed as an engineer at the Savannah River plant of E. I. Du Pont de Nemours & Co. His new address is 116 Hudson Road, Aiken, S. C.

Marlin E. Weakly has resigned as product test engineer in the engineering test and development department at the East Moline Works of International Harvester Co., to accept employment as a junior designer in the product engineering department of the John Deere Harvester Works, East Moline, Illinois.

James A. Luscombe, who more recently has been engineer-in-charge of the Oklahoma Co-op Ginning Investigation, Oklahoma Cotton Research Station, Chickasha, on June 1 assumed the duties of engineer-in-charge of the Southeast Cotton Ginning Research Laboratory at Clemson, S. C.

Jack L. Sparks has resigned as irrigation engineer with the firm Michael Baker, Jr., Inc., to accept appointment with the University of Maryland U.S. Operations Mission to British Guiana. He will be employed in the capacity of irrigation and drainage engineer.

Daniel R. Donnelor has been transferred from the position of agricultural engineer, U.S. Soil Conservation Service, Oswego City, Kans., to the position of survey and planning engineer on the Little Delaware Mission Watershed in Brown County, Kans. He will be located at Hiawatha, Kans.

James H. Strickler, who has been employed as an electric development representative of TVA, has recently accepted appointment on the agricultural engineering staff of Virginia Polytechnic Institute, Blacksburg.

Merle H. Peterson, a project engineer at the Racine, Wis., works of Massey-Harris-Ferguson, Inc., was recently promoted to chief engineer of the tillage division at the Racine works. (Continued on page 418)

ASAE Quad City Section officers at the annual meeting of the Section April 22. (Standing, left to right) C. S. Morrison, 1954-55 chairman, and new 1955-56 officers: G. W. Berryhill, secretary; M. E. Weakly, chairman; M. L. Love, treasurer; R. G. Morgan, chairman, nominating committee; R. E. Harrington, vice-chairman, and E. G. Rowlett, vice-chairman

National and section officers at the meeting of the ASAE Rocky Mountain Section at Logan, Utah, April 8 and 9. (Seated, left to right) ASAE Vice-President J. W. Martin, C. W. Lauritzen, soil scientist, U.S. Department of Agriculture, and ASAE President Geo. B. Nutt. (Standing, left to right) New Section officers for 1955-56—E. G. Hanson, chairman; G. O. Woodward, secretary, and N. A. Evans, vice-chairman—and S. H. Daines, program chairman for 1954-55 year

PEORIA MALLEABLE CASTINGS

"have a hand
in the
harvest"

with

GLEANER-BALDWIN COMBINES

Famous for performance and stamina, the Allis-Chalmers Gleaner-Baldwin line of combines is noted for its high quality construction. At many important points Peoria Malleable Castings are used.

Peoria Malleable castings provide an attractive part that is durable and dependable. And, very often, their cost is less than the labor and material involved in making a weldment or a forging.

Write for complete information. If you would like a definite quotation, at no obligation, enclose specifications with your letter.

A Gleaner-Baldwin self-propelled combine provides fast, efficient harvesting on this Midwestern farm.

News of ASAE Members

(Continued from page 416)

John D. Cowsar, until recently employed as an agricultural engineer with Black, Silvalls and Bryson, Inc., at Kansas City, Mo., recently accepted appointment as instructor in agricultural engineering at the A. & M. College of Texas, College Station. In addition to his teaching duties he will be engaged in grain storage research.

Everett W. Todd, who has been chief engineer in the tillage division at the Racine, Wis., works of Massey-Harris-Ferguson, Inc., was recently appointed chief project engineer of the planting and cultivating engineering group at the company's Detroit works.

Paul C. Mortenson, who has been serving as executive engineer in the engineering department at the Racine, Wis., works of Massey-Harris-Ferguson, Inc., has been transferred to the engineering department of the company's works at Detroit, Mich., where he will serve as administrative engineer for the Western Hemisphere engineering division of the company.

Glenn M. Haslett, Jr., who has been employed as an agricultural representative of Caterpillar Tractor Company, together with Jim Watkins, a civil engineer, has recently formed the H. and W. Engineering Company of Indianola, Miss., which is offering farmers in that area a complete service in

irrigation and drainage engineering, irrigation and drainage construction, and power farming.

William E. Swenson, who has been design correlator for the various engineering departments of the Minneapolis-Moline Company, was recently named assistant director of engineering for the company.

Mr. Swenson, following engineering studies at the University of Minnesota, joined the Minneapolis-Moline organization in 1926. After three years as a draftsman, he specialized in engine design, and in 1944 was named assistant chief engineer of automotive engineering. He became engineering coordinator in 1954 and has been engaged in integrating design of Minneapolis-Moline tractors, farm machines, and implements made at the company's plants at Minneapolis and Hopkins, Minn., Moline, Ill., and Louisville, Ky.

Marshall W. Loupo, until recently irrigation engineer for the Carloss Well Supply Co., Memphis, is now manager of the irrigation division of Tri-State Albany, Inc., a retail dealership at Albany, Ga.

Robert W. Loudon, formerly vice-president and general manager of the farm line, The Loudon Machinery Co., has announced that the newly formed Fairway-Factory Division of the Robert W. Loudon Co. has been appointed exclusive Iowa distributor of the Westcoaster line of electric cars for golf and industry.

NECROLOGY

Charles Deere Wiman, a member of ASAE since 1929, and president of the Deere & Company since 1928 (with exception of two and one-half years during World War II), and a great grandson of John Deere, the company's founder, died in Tucson, Ariz., May 12, after an extended illness.

CHARLES D. WIMAN

Widely known as a leader in the farm equipment industry, and former president of the Farm Equipment Institute, Mr. Wiman also had many other business interests. He had been active in the International Chamber of Commerce, and at the time of his death was a member of boards of directors of various organizations, including the Continental Illinois National Bank & Trust Co. of Chicago, the Rock Island Lines, the Hilton Hotels Corp., and the Protection Mutual Insurance Co.

Mr. Wiman was born on Staten Island, N. Y., February 11, 1892, the son of William Dwight and Anna Caroline Deere Wiman. His mother was a daughter of Charles H. Deere, only son of John Deere and second president of Deere & Co. He married Pattie Harris Southall in Huntsville, Ala., April 12, 1920. She survives, as do their two daughters, Mrs. William A. Hewitt of Moline, Ill., and Mrs. William M. Brinton of San Francisco, and three grandchildren.

Mr. Wiman joined the John Deere organization in 1915, and was a shop employee at the John Deere Plow Works for a brief period before returning to Yale University as assistant coach of the Yale crew, of which he was a former member. When the National Guard was called to the Mexican

border in 1916, he enlisted in the Civilian Military Aviation Training Camp at Governor's Island, N. Y. He received a pilot's license in the Aero Club of America and flew for three months before being injured in an airplane accident in September, 1916.

Following his recovery he returned to Deere & Co., but shortly before the United States entered World War I he enlisted in the regular army and was commissioned as a second lieutenant. Promoted to first lieutenant and then captain of field artillery, he served with the Third Field Artillery which for eleven months was in the Sixth Division of the American Expeditionary Forces.

Released from the army in October, 1919, Mr. Wiman was a shop employee, later superintendent, and then general manager of the Union Malleable Iron Co., a Deere & Co. subsidiary. In 1924 he was elected vice-president in charge of factory operations for Deere & Co., and in 1928 he became the company's fourth president.

In June, 1942, Mr. Wiman resigned the presidency of Deere & Co. in order to join the staff of General Levin H. Campbell, chief of ordnance, with the rank of colonel. In January, 1944, he was placed on inactive status by the army at the request of the War Production Board, in order to become director of the WPB farm machinery and equipment division. He held that position until July 7, 1944, when he asked to be relieved of his duties in order to regain his health after a severe attack of pneumonia.

Mr. Wiman returned to Deere & Co. in November, 1944, and was re-elected president. Burton F. Peek, president during Mr. Wiman's absence, was named chairman of the board.

Funeral services were held in Moline, May 16. Burial was in the Deere family lot in Moline's Riverside Cemetery, near the graves of John and Charles Deere, Mr. Wiman's great grandfather and grandfather.

NEW BOOKS

(Continued from page 408)

SAE Handbook (1955 edition). Cloth, 1094 pages, 8½ x 11 inches. Illustrated and indexed. Society of Automotive Engineers (29 W. 39th St., New York 18, N. Y.)

New standards, recommended practices and reports, included in this edition apply to classification of rigid plastic molding materials, multi-viscosity number oils, diesel fuels, fuel injection tubing, fuel supply connections, semiautomatic headlamp-beam switching devices, motor truck instrument panel grouping, rear wheel guards, truck overall widths across dual tires, turning ability and off-tracking, fuel systems, wheel mounting elements for 8-bolt, 8-in bolt circle farm equipment disk wheels, interchangeability of disc halves for agricultural press and gage wheels, agricultural tractor power take-off definitions and terminology, industrial tractor mounted equipment nomenclature (bulldozer), construction and industrial vehicle test codes, and hydraulic power pump test code.

Handbook of Drainage and Construction Products. 592 pages; 380 illustrations; 6 x 9 inches. Published by Armo Drainage & Metal Products, Inc., Middletown, Ohio. \$5 postpaid.

This new edition of a book that was first published a quarter of a century ago is a comprehensive technical treatment of the design and engineering application of a number of widely used drainage and construction products.

Purpose of the book is to aid engineers in solving drainage problems and related engineering construction problems, also to enlighten students in practical modern drainage and other construction problems.

In 10 sections and 64 concisely written chapters it covers strength research; strength design; durability studies; durability design; economic factors; design principles and practice; subsurface drainage; special drainage problems; miscellaneous problems; and installation instructions. In addition there is a section of conversion tables and general tables, an appendix summarizing research on underground conduits, and a well organized index for quick and easy reference.

A typical section, Design Principles and Practices, indicates the thoroughness of the work. The thirteen chapters of this section deal with hydrology; design of open channels; theory of critical flow; design of culverts or cross drains for size and shape; culvert location and length; highway surface drainage; railway surface drainage; culverts under levees and dikes; end finish of culverts; design of sewers for size; hydraulics of sewers; sewer appurtenances; and part circle culverts.

Each chapter is summarized at the beginning and each illustration is referred to in the text.

The Heating Ventilating Air Conditioning Guide 1955 (33rd edition). American Society of Heating and Air-Conditioning Engineers, 62 Worth Street, New York 13, New York, \$12.00. This is larger and improved in content over previous editions. The technical section is 1160 pages.

Changes include several rewritten chapters, a new chapter on schoolhouse heating and ventilating, new information on heating systems using high temperature hot water, and reorganized design information on thermal conductivities and conductances for pipe insulation and building materials.

International Harvester's McCormick FARMALL Tractors utilize ductile cast iron parts. Fast-Hitch latches are typical. They withstand not only wear, but also sudden shock loads when latches are tripped.

All sorts of parts for International Harvester farm machinery are produced in ductile cast iron. They range from small spur gears on corn pickers to main drive sprockets for roller chain... from steering knuckle arms to bolster forks.

For Shock-Proof farm machinery parts Cast them in Ductile Iron

Widely used by International Harvester

Imagine an iron, as cast, with tensile strength up to 110,000 pounds per square inch...

And up to 210,000 pounds per square inch when heat treated!

That's what ductile cast iron offers you. It's a type of cast iron that combines remarkable properties. High toughness and load-carrying ability. High resistance to wear, shock and vibration. And double the stiffness of gray cast iron.

You can see why International Harvester engineers use ductile cast iron widely in farm equipment.

They find it easy to cast into intricate shapes. They can readily machine it. They can anneal it for maximum ductility... normalize it for both high strength and toughness. They can oil quench and temper it for strength or hardness. In fact, they can raise its hardness to more than 500 BHN, by heat treatment.

See how this economical iron... several times stronger than gray cast iron, and up to 12 times tougher... can improve *your* products. You may find several practical answers in the new INCO booklet "DUCTILE IRON, The Cast Iron THAT CAN BE BENT!" A copy is yours for the asking. Write for it now.

Back of the JOHN DEERE No. 55 Combine is a story of ...

Oil Power

HYDRECO Oil Power

The famous HYDRECO Four-Bolt design Hydraulic Pump provides Oil Power on the John Deere No. 55 Self-Propelled Combine to position the Auger Platform and control the Variable Speed Drive. This model 1506 Pump delivers 3.3 gpm at 1200 rpm with pressures to 1500 psi...other models to 130 gpm.

Build the hydraulic circuit around the dependability of HYDRECO components. More and more design engineers find this premise leads to successful performance in service whether the application be farm equipment, machine tools, materials handling or construction machinery.

HYDRECO Oil Power ... Pumps, Motors, Valves and Cylinders have one important characteristic in common ... they're dependable. And the engineering that contributes this dependability may be relied upon to make significant contributions to your present and projected hydraulic problems.

Pressure Balanced wear plates maintain a fixed clearance between wear plates and gear faces regardless of pressure. This feature in HYDRECO Pumps and Motors minimizes oil slippage and power loss... volumetric efficiency and mechanical efficiency remain high!

Write for brochures on HYDRECO Pumps, Motors, Valves and Cylinders.

68 Years of Continuous Service
to American Industry

MILWAUKEE WROT WASHERS

**SINCE
1887**

Our equipment for handling contract production of stampings includes presses for blanking, forming, drawing, shearing and extruding. In many cases it is possible to produce stampings at a lower cost than they can be produced in your own plant, with our own equipment. Our own tool and die-making shop enables us to make up the necessary tools to fit your specifications.

We are equipped to furnish stampings in any desired materials and finishes, ranging in size from small parts to large heavy-gauge pieces. Our engineering staff will be glad to co-operate with you in every way consistent with economical and efficient production.

• • •

Send us your blueprints for quotations on special washers and stampings made to your individual specifications. Write for copy of 76-page Catalog "30" with tool list and complete round washer specifications.

In terms of "satisfaction to the customer" the dominant leadership of Wrought Washer Mfg. Company in this specialized field represents not only a thoroughly dependable source of supply to meet all your requirements for Standard and Special Washers, but of equal importance, it carries with it a wealth of technical know-how dealing with a wide variety of production and design problems . . . available to you as a gratis service. More than 25,000 sets of dies "in stock" at our plant offer the greatest range of selectivity.

Accuracy cuts cost.
Less than 1 hour machining time is required
per unit assembly with Unitcastings.

*Accuracy..
Appearance..
and
Dependability*

..ADD UP TO TOP QUALITY PRODUCT!

A nationally known manufacturer of house trailer tow-bar mechanisms keeps quality up and costs down by specifying *Unitcastings*. Dimensional accuracy, internal soundness and good surface appearance hold finishing costs to a minimum and help retain customer acceptance. In less than six years of production and over 202,000 parts later, less than 1/2 of 1% of the total castings shipped have been returned for any reason.

Beginning with the original design of the castings, Unitcast's engineering service has kept pace too, by continually modernizing the design to suit automobile chassis improvements. This is just one of the many Unitcast Foundry Engineering Services available to our customers.

Let Unitcast help you modernize your product by including foundry standards in the design. Keep your production cost competitive...write today!

Applicants for Membership

The following is a list of recent applicants for membership in the American Society of Agricultural Engineers. Members of the Society are urged to send information relative to applicants for consideration of the Council prior to election.

Andrews, H. A.—Assistant zone manager, International Harvester Co. (Mail) Box 47, Milldale, Conn.

Beaumier, Marcel—Manager, farm machinery div., La Cooperative Federee de Quebec, 105 St. Paul St., E., Montreal, Quebec, Canada

Blight, David P.—Research assistant in agricultural engineering, Stephenson Bldg., King's College, Newcastle-on-Tyne 2, England

Body, John H.—Student in agricultural engineering, Pennsylvania State University. (Mail) Yellow House, Pa.

Boston, William J.—Student in agricultural engineering, Oklahoma A. & M. College, Stillwater, Okla. (Mail) 19-1 Brumley

Boutwell, Robert B.—Student in agricultural engineering, University of Vermont, Burlington, Vt. (Mail) 21 University Rd.

Carnahan, Herbert E.—Student in agricultural engineering, California State Polytechnic College, San Luis Obispo, Calif. (Mail) 59 Vetville

Case, Eugene H.—Director of college and university relations, Deere & Co. (Mail) 140 Norfolk Rd., Waterloo, Iowa

Coronado, Francisco X.—1st Lt., USAF. (Mail) Box 6234, Mather Field, Calif.

Crafts, Barry S.—Student in agricultural engineering, University of Maine. (Mail) Sangerville, Me.

Craven, Wilmer C.—Manager, diesel engine and farm machinery branch, E. F. Craven Co., Greensboro, N. C. (Mail) 2513 Oakcrest Ave.

Davis, Charles A. Jr.—Design engineer, U.S. Forest Service, Yreka, Calif.

Dordahl, Alvin M.—Engineering representative, National Rain Bird Sales & Engineering Corp., Azusa, Calif. (Mail) P.O. Box 46

Ekstedt, William C.—Assistant to agriculturist, Western Massachusetts Electric Co., 73 State St., Springfield, Mass.

Evans, Layton C.—Agricultural engineer, The John Deere Plow Co., 339 S. Front St., Memphis 3, Tenn.

Fink, Harry A. Jr.—Student engineer, product development dept., Deere & Co. (Mail) RR 11, Lafayette, Ind.

Florin, James S.—Assistant engineer, Allis-Chalmers Manufacturing Co. (Mail) 654 Johnson St., Winona, Minn.

Frost, Gerald G. Jr.—Ensign, U.S. Navy. (Mail) 124 N. Broad St., Norwich, N.Y.

Hawkins, Clifton J.—Student in agricultural engineering, Mississippi State College. (Mail) RR 2, Box 67, Clarksdale, Miss.

Hays, Carl V.—USAF. (Mail) General Delivery, Pennsylvania State University, University Park, Pa.

Huber, Albert L.—U.S. Navy. (Mail) RR 1, Meridian, Ida.

James, Howell N.—Product engineer, International Harvester Co. (Mail) 1000 22nd St., Moline, Ill.

With a Winch, it's a Cinch TO STACK BALED HAY IN BARN

RAY GLASS, who farms 240 acres, is mighty handy with tools and welding equipment. He designed and built this portable winch which is powered by a small, air-cooled engine. He uses it to pick up baled hay in the field and to stack the bales in the barn, eliminating hard labor. Mr. Glass, like keen farmers and ranchers from coast to coast, has found that *it pays to farm with Texaco products.*

Ray Glass (right), near Carroll, Iowa, shows Texaco Distributor Sam Hyland the portable gasoline motor-powered winch which he put together to save labor of stacking baled hay in barn. Bearings are lubricated with Marfak, because Marfak sticks better and longer, seals out dust and moisture.

C. R. Grigg (right), who farms over 700 acres near Sherman, Texas, has used Texaco products for fifteen years. He gets longer trouble-free life and better performance from his engines with Advanced Custom-Made Havoline Motor Oil. It's the best motor oil money can buy. Popular Texaco Consignee E. B. Chapman is shown on left.

★ ★ ★

"We've found we can depend on the high quality of Texaco products," says Irvin (Spud) Johnston (left), well-known potato farmer of Lynden, Wash. "That's why we have used them for over seven years." Texaco Consignee E. A. Hofman (right) has just delivered some Texaco Universal Gear Lubricant EP to Mr. Johnston. It provides extra protection to transmission and differential.

IN TOWN OR ON THE HIGHWAY— there is a nearby Texaco Dealer. He has new top octane Sky Chief gasoline, Super-Charged with Petrox, to give maximum power and reduce engine wear...famous Fire Chief, at regular gasoline prices, both 100 per cent Climate-Controlled for top performance...Advanced Custom-Made Havoline Motor Oil and Marfak lubricant.

An Interesting Small Engine Application to do a BIG JOB!

WISCONSIN-POWERED Self-Propelled Grain Swather

This is the Model TF 2-cylinder Wisconsin Heavy-Duty Air-Cooled Engine that supplies complete power for the Owatonna Grain Swather illustrated above—3 1/2" bore x 3 1/4" stroke, 53.9 cu. in. displ., 8.7 to 14.6 hp., 1400 to 2600 rpm. Larger size swathers are powered by the Model VF4 V-type, 4-cylinder Wisconsin Engine.

Typical of the practical ingenuity employed by farm equipment designers and builders for the most advantageous utilization of engine power is this Owatonna Grain Swather, made by Owatonna Mfg. Co., Owatonna, Minn.

A unique feature of this Center-Delivery Grain Swather is that it opens up all types of grain fields without running down standing grain. Mechanically operated aprons at both ends of the machine carry the grain, as cut, to the center opening, depositing it in a compact, uniform swath for clean, easy combining. The floating cutter bar extends over the entire length of the machine, forward of the wheels.

A remarkable feature of this equipment is that an engine as small as a 2-cylinder Wisconsin furnishes the necessary power both for *propelling* and *operating* this big machine. It's an assignment that calls for heavy-duty Lugging Power and foolproof AIR-COOLING at temperatures up to 140° F. Here is a perfect example of *Power to Fit the Machine, Power to Fit the Job!*

Wisconsin Air-cooled Engines are available in 12 sizes in 4-cycle single cylinder, 2- and 4-cylinder models, in a 3 to 36 hp. range.

WISCONSIN MOTOR CORPORATION

World's Largest Builders of Heavy-Duty Air-Cooled Engines

900 SERIES
Full 3-Plow Power

They're **New** —they're **Tricycles** —and they're **FORDS**

**NEW! Power Adjusted
Rear Wheels**

**NEW! High Crop
Clearance, with Safety**

**NEW! Tailored Traction
with exclusive
Vari-Weight System**

**Both 2- and 4-Row
Planting and
Cultivating Equipment**

You have perhaps wondered what would happen if Ford engineering skill and long experience went all out to build really new, really better tricycle tractors. Now you can find out!

Here, for the first time, are tricycle tractors built by Ford...in two power series. Both fitted for 4-row and 2-row front-mounted cultivators and planters and for 1-row and 2-row mounted corn pickers and harvesters. One series with full 3-plow power, the other with full 2-plow power.

A new combination of *high* crop clearance and *low* driver seat makes

these tractors the safest as well as the *easiest handling* tricycles ever. There's an ingenious Vari-Weight System of wheel and front-end weights available to give true "Tailored Traction."

Enough other great features to fill a book! And this book is waiting for you at your nearby Ford Tractor and Implement Dealer's. Drop in, ask for it and have a good look at Ford's new Tricycle Tractors soon.

PERSONNEL SERVICE BULLETIN

NOTE: In this bulletin the following listings current and previously reported are not repeated in detail; for further information see the issue of AGRICULTURAL ENGINEERING indicated.

POSITIONS OPEN—JANUARY—O-437-667, 438-668, 447-672. FEBRUARY—O-19-704, 32-705, 33-706, 18-709. MARCH—O-55-710, 61-713, 71-714, 87-715. APRIL—O-120-716, 142-717, 125-718, 155-719, 143-720, 173-721. MAY—O-200-722, 197-723, 180-724, 196-725, 205-726, 214-727, 214-728.

POSITIONS WANTED—DECEMBER—W-391-164, 411-166. 1955—MARCH—W-17-2, 48-4, 84-5, 27-6. APRIL—W-114-8, 129-9, 4-10, 133-11, 134-12, 67-14. MAY—W-154-15, 165-16, 177-17, 185-18, 176-19, 193-20, 206-21, 182-22, 213-23.

NEW POSITIONS OPEN

AGRICULTURAL ENGINEER (rating assistant professor and assistant agricultural engineer in the agricultural experiment station), for teaching soil and water conservation and either farm structures or farm power and machinery; and for research in irrigation and drainage, in a land grant college in a north central state. Age 25-40. MS deg in agricultural engineering, or equivalent. Several years of teaching, research, or extension work in soil and water field. Good personality and interest in teaching and research. Good opportunity for advancement. The man selected will be responsible for developing the teaching and research programs in the soil and water field. New agricultural engineering building with well equipped soil and water conservation laboratory. Salary open. O-243-729

AGRICULTURAL or mechanical engineer to head up development department in young aggressive sprinkler irrigation corporation. Residence to be required in the state of Washington and a small amount of traveling would be necessary. Engineer should have excellent background in manufacturing processes and should be capable of carrying new ideas through the development and experimental stages to final production. Should be somewhat well acquainted with the sprinkler irrigation field. Salary is open and dependent entirely upon the ability of the individual. Opportunities for further advancement are excellent. State background and experience in detail in application. O-235-730

AGRICULTURAL ENGINEER or soils specialist for settler assistance work with new settlers in the Columbia Basin. Employment with Washington State College Extension Service in cooperation with the Bureau of Reclamation. Work consists of complete planning and layout of farm fields and farm irrigation systems, technical advice in clearing farm units, determining the amount of leveling necessary, staking the land for leveling and checking the leveling operation, technical advice and assistance in irrigation practices and use of water control and distribution devices to assure efficient use of irrigation water. Background of soils and agricultural engineering desirable. Also experience on irrigated farm important. Salary range depending upon experience, \$3600 to \$4500 beginning salary. Six months training period given to all employees. O-244-731

EXTENSION SPECIALIST in wood and metal working, to develop and carry out wood and metal working programs with 4-H Club leaders and members in a midwestern state. Excellent opportunity for a person interested in youth work. Good opportunities for advancement. Salary up to \$6,500 for 12 mo, with one month vacation. O-268-732

AGRICULTURAL ENGINEER (rating associate extension agricultural engineer) to handle 4-H tractor program and develop program for adult farmers on choice, use, care, and maintenance of farm machinery and power equipment in an eastern state. Age 26-40. BS deg in agricultural engineering, or equivalent, and MS deg or equivalent qualifying field experience, preferably in extension work or farm equipment sales. Able to talk and work with farm people and the farm equipment industry. Man selected will be fully responsible for extension project in farm power and machinery, and will be associated with an extension staff of six others working on other agricultural engineering subject matter. Excellent opportunity to develop an outstanding program. Annual leave 26 days. Salary increases on merit basis. Starting salary about \$5280. O-248-733

SEALMASTER Catalog 454.

SEALMASTER'S *Exclusive* combination of features put added sales power into the products you sell!

One of the most significant trends in the farm field during the past year has been the increasing demand for quality in farm machinery. Initial purchasing price is of importance to the farmer but operational expense over the long haul is the **big** thing. The machinery market is competitive and the farmer has become a careful buyer. He's interested in a piece of machinery that will give him top performance and eliminate costly hours of maintenance. No component you build into your product will mean more to its efficient performance than the bearing units carrying the load. Insist on SEALMASTER and be sure!

NEW POSITIONS WANTED

AGRICULTURAL ENGINEER for development, sales, or service in soil and water or product processing field with manufacturer, processor, distributor, consultant, farming operation or trade association, anywhere in U.S.A. Married. Age 34. No disability. BS deg in agricultural engineering, 1949, University of Minnesota. Farm background. Hydraulic engineer with U.S. Geological Survey since graduation. War enlisted and commissioned service in Navy, 4 yr. Available September 1. Salary open. W-179-24

AGRICULTURAL ENGINEER for development and research in soil and water field, with manufacturer or processor, anywhere in U.S.A. Married. Age 40. No disability. BS deg in mechanical engineering, 1940, University of Beograd (Yugoslavia). Ph.D., 1945, University of Geneva, Switzerland. Military service in

Yugoslavia, 1940-41. Experience in research with Monopol of Tobacco, Beograd, University of Beograd, and in Perugia, Italy, 1946-49. Immigrant in U.S.A. Available on reasonable notice. Salary open. W-203-25

AGRICULTURAL ENGINEER for design, research, development or management in power and machinery or soil and water field with manufacturer, trade association or farming operation in Midwest. Limited travel. Prefer some outdoor work. Married. Age 28. No disability. BS deg in agricultural engineering, 1951, Purdue University. Farm background. Soil Conservation Service 6 mo as engineer trainee. Army service 2 yr, including 19 mo as engineering assistant in research and development on automotive equipment. Catalog technician and designer with manufacturer of farm equipment. Available now. Salary \$425 mo. W-242-26

AGRICULTURAL ENGINEER for design, development, or research in soil and water field with industry or public service, preferably in Southeast. Prefer moderate traveling. Married. Age 31. No disability. BS deg, 1951, soil con-

servation and agronomy; MS deg 1952, soil physics and agronomy, both at Ohio State University. Limited farm experience. Tool designer, 3 yr; civil engineering, 2 yr; soils mechanic, 4 mo; soil physics research 2 yr. Currently graduate assistant. Available August 1. Salary \$5000. W-247-27

AGRICULTURAL ENGINEER for design, development, or research in soil and water field, with industry or public service in Northwest or Canada. Prefer travel and outdoor work. Married. Age 24. Wear glasses for office work. BS deg in agriculture, 1953, University of Saskatchewan. Farm background. With Canadian PFRA 2 yr in maintenance and development work on irrigation projects. Available on reasonable notice. Salary \$3800-4200. W-250-28

AGRICULTURAL ENGINEER for methods development, application of industrial engineering techniques to agricultural production and processing, and supervision of production and processing activities, fields of product processing and farm structures, with processor, distributor, farming operation or public service agency, anywhere in U.S.A. Will consider overseas assignment. Single. Age 26. No disability. BS deg, 1951, MS deg in agricultural engineering, 1955, Rutgers University. Farm background. Graduate research program concentrated on materials handling aspects of artificial drying of crops. Additional experience in supervision of construction activities, site planning, structural rehabilitation, maintenance of facilities, coordination between contractors, supervision of skilled and unskilled labor crews, instruction in surveying and land reclamation course laboratory. Commissioned service in U.S. Air Force 21 mo, partly overseas with responsibility for truck fleet operations in mass handling of bulk and packaged building materials, vehicle repair parts, earthmoving equipment and spare parts. Available on 30 days notice. Salary open. W-252-29

AGRICULTURAL ENGINEER for college teaching and research in rural electric field, anywhere in U.S.A. Married. Age 43. No disability. BS deg, 1940, University of New Hampshire. MS deg, 1952, Virginia Polytechnic Institute. PhD expected September 1955, Cornell University. Experience one year as teacher of vocational agriculture. Research assistant and instructor 1948-55. War noncommissioned and commissioned service 5 yr. in U.S. Air Force Communications. Available September 15. Salary open. W-245-30

AGRICULTURAL ENGINEER for development, sales, service or management in power and machinery, soil and water, fertilizers or agricultural chemicals, with manufacturer, processor, distributor, consultant, farming operation, or trade association, preferably West Coast or foreign but will consider other locations. Willing to travel. Married. Age 25. Slightly disabled right hand. BS deg in agricultural engineering, 1951, Oregon State College. Work completed for M Ag deg in agricultural engineering, soils, and economics. Farm background. Summer work as mechanic and as weed control research assistant. Present work, plant manager and salesman for aqua ammonia and agricultural chemicals plant. Available on 30 days notice. Salary \$450 mo. W-263-31

AGRICULTURAL ENGINEER for design, development, or research in power and machinery or rural electric field with industry or public service, anywhere in USA. Married. Age 25. No disability. BS deg in agricultural engineering, 1953, University of Massachusetts. New England dairy farm background. Agent, USDA farm electrification section, 9 mo. Operated father's dairy farm 6 mo, during his illness. Instructor in research, forage harvesting mechanization, University of Massachusetts, 6 mo. Available after July 1. Salary \$400 mo. W-208-32

We've put your TRACTOR GAUGES on a NEW cushion

Here's the gauge that takes rough riding, tough pounding and jarring impact whenever it's used without losing its accuracy and dependability. Rochester Tractor Gauges are cushioned by vibration and pulsation dampeners—

BUILT INTO THE MECHANISM OF EACH GAUGE!

Pressure Gauges: Stem provided with pulsation dampener to minimize the effect of pulsating pressures.

Temperature Gauges: Capillary tubing is completely armored and cushioned at both ends in neoprene to withstand vibration.

Restrained Diaphragm Pressure Gauges: Over the pressure sensitive diaphragm is a backplate absorbing overload pressure and stopping the diaphragm travel, arresting strain on the gauge movement if gauge is overloaded.

Those are some of the plus features that make Rochester Tractor Gauges the most accurate, safest, most dependable heavy-duty gauge designed—with ample provision for handling emergency overloading and safety.

For the leading manufacturers of tractors, Rochester Manufacturing designs and produces specialized gauges in volume. Call in your Rochester Sales Engineer or write directly to the company for further information.

with **RAIN BIRDS**

in the field!

No. 30

That's why on farms and ranches across the nation . . . around the world, you'll find more RAIN BIRDS than any other type sprinkler.

Made with a minimum of moving parts to wear or require servicing, RAIN BIRDS stay on the job, performing day in and day out with maximum efficiency and dependability.

Remember, if it hasn't the name . . . it isn't the same. Specify **RAIN BIRD**!

the **BADGE** of him who **BELONGS**

DESPITE the *presumption* it sets up, mere membership in the American Society of Agricultural Engineers is no *proof* of a man's high rank in technical talent. It does prove that he has met certain minimum requirements and has earned the esteem of colleagues who sponsored his application for membership.

But the Society emblem is *evidence* that native talent, be it great or small, is enriched by fraternity with the personalities whose minds fuse to form the pattern of progress in the methods and mechanics of agriculture. The wearer of the emblem waits not for the debut of an idea, but is present at its birth and helps to guide its growth.

Be you novice or veteran, your membership in the organized profession adds something to your efficiency, your vision, your influence as an individual engineer. The Society symbol on your lapel is token that you "belong". Wear it.

STYLES AND PRICES OF ASAE EMBLEMS

With blue ground for Fellows, Members, and Associate Members — furnished either in pin with safety clasp or lapel button — \$3.50 each.

With red ground for Affiliates — furnished only in pin with safety clasp — \$3.50 each.

Send orders to ASAE, St. Joseph, Michigan.

Here's how to build **CONCRETE BLOCK JOIST FLOORS**

The popularity of concrete block joist floors for farm homes and other buildings is rapidly increasing. Such floors are easy to build with either plain or soffit type block as filler units, and are practical for single or multiple spans from 10 to 17 ft. in length.

The above illustration shows the six simple construction steps in building concrete block joist floors:

- 1** Build exterior wall to height of floor, including one course of 4-in. solid concrete block as shown in drawing.
- 2** Erect formwork of parallel planks (adequately supported by posts and ledgers) for supporting the filler units and the concrete slab.
- 3** Lay rows of block on planks, with cores running horizontally. The joints between block in adjacent rows may be staggered or continuous.
- 4** Install reinforcing bars for the cast-in-place joists as per design table.* Also place conduits for wires, ventilating, plumbing and heating.
- 5** Set a continuous strip of 1-in. waterproof insulation board—as deep as the floor is to be—around the edge of the entire floor.
- 6** Place concrete for joists and slab and moist cure for 5 to 7 days before removing formwork. The floor is firesafe and an ideal base for any floor finish desired. The flat underside can be painted, plastered or left exposed as desired.

*Write for free, illustrated booklet explaining the design and construction of concrete block joist floors. Distributed only in U. S. and Canada.

PORTLAND CEMENT ASSOCIATION

Dept. A6-1, 33 W. Grand Ave., Chicago 10, Ill.

DURKEE-ATWOOD V-BELT QUIZ

**DO YOU
KNOW HOW
TO PREVENT
SLIPPING
V-BELTS?**

1. Check for over-heating.
2. Check for excessive wearing of sheaves.
3. Check for excessive power loss in driven unit.
4. Check for loose belts in drive. (Sales plug: If none of the above solutions corrects the slipping, consult your local D-A distributor).

FREE COPY! Handy Tips on V-belts and V-drives
See your D-A distributor or write Dept. AE-6 for catalog that includes conversion tables, engineering data, latest Rubber Manufacturers Association horsepower ratings, drive selections and helpful Do's and Don'ts of V-belt operation.

Unusual Opportunity for an Ag. Engineer

A position is available in the editorial department of a long-established agricultural paper. Some of the essential requirements are:

A farm and agricultural engineering background—ability to handle detail work—to work with figures quickly and accurately—to be able to express oneself clearly so as to write reports of meetings, of interviews, and to describe appraisingly advances in farm methods and equipment. Above all, the man who fills this position must be able to meet a deadline.

Address Box AE-55, c/o Agricultural Engineering, St. Joseph, Michigan.

This "wardrobe" fits standard ball bearings to CUSTOM OCCASIONS

Versatile is the word for New Departure standard ball bearings! For these bearings may be obtained in a wide range of standard variations (as shown below), opening a tremendous range of uses to the engineer. In other words, a standard bearing has a "wardrobe" which fits it for very nearly any occasion!

New Departure Single Row Conrad-type bearings, with standard variations available, illustrate the "wardrobe" principle which makes these ball bearings, with their dual load-carrying ability, the most readily adaptable of all bearing types.

Virtually any mounting or operating requirement within a wide range of usage is met perfectly by a standard New Departure ball bearing, in conjunction with shields, seals, snap ring, or combinations thereof. Shields protect the bearing from ordinary dirt both before and after mounting and, in many cases, provide adequate retention of lubricant. Seals give positive protection against dirt of every kind and make possible enclosed lubrication for extended or even lifetime service. Snap rings allow positive location in housings lacking inside shoulders. Whenever a design or engineering problem involves ball bearings, think of New Departure. Highly experienced ball bearing engineers are always ready to work with you.

How I-H Engineers Handle Thrust Loads, Eliminate Wheel Hub Machining on Plow Furrow Wheel

WHEN International Harvester engineers developed this new rear furrow wheel, they didn't have one problem to solve—they had four. How to handle tremendous thrust loads while operating in deep dirt; how to keep that dirt out of the bearings; how to design a bearing assembly that would permit the plow to be towed at full tractor speeds on the open road; how to cut production costs. One engineering feature solved all of these problems. The engineers mounted the wheel on Timken® tapered roller bearings.

Timken bearings not only handle the tough thrust loads, but the radial load as well. Their tapered construction enables them to take any combination of thrust and radial loads. More effective closures are possible because Timken bearings hold housings and shafts concentric. Dirt stays out—lubricant stays in.

Ease of operation is assured whether the plow's being towed to the job or pulled in the field. The true rolling

motion and precision manufacture of Timken bearings practically eliminate friction.

And manufacturing is one step simpler, too. For this special application, a tube assembly is furnished by the Timken Company and the tube is welded to the flange.

Wheel hub machining is completely eliminated.

For more information, write now for your free copy of "Timken Roller Bearing Practice in Current Farm Machinery Applications". The Timken Roller Bearing Company, Canton 6, Ohio. Canadian plant: St. Thomas, Ontario. Cable address: "TIMROSCO".
